# 6.33 Application Notes

## 6.33.1 Memory Configuration

**RM/RMA/RMB**

Read-Write margin Input. This input is used for setting the ReadWrite margin. It programs the sense amp differential setting and write time window which allows the trade off between speed and robustness.

**RA**

Read Assist Pins to control WL under-drive.

**WA**

WA[1] Write assist enable pin (Active High). WA[0:0] Write Assist pin to control negative voltage on SRAM bitline.

**WPULSE**

Write Assist Pulse pins. These pins control the start time of the bitline negative coupling.

**WMD/WMDA/WMDB**

Rockchip Confidencial

When enabled it is used to add more delay in the Write cycle for internal clock pulse. No change in the read cycle internal clock pulse.

**LS**
Light Sleep Input. When this pin is active then memory goes into low leakage mode, there is no change in the output state.

**TEST_RNM**
When this pin is high Memory will go in idle state and bit-lines are pre-charged high.

**TEST1**
Test pin to bypass self-timed circuit. The external clock controls the read and write control signals.

**TESTRWM**
Test mode for read write margin control.

Rockchip Confidencial

# Chapter 7 Power Management Unit (PMU)

## 7.1 Overview

In order to meet low power requirements, a power management unit (PMU) is designed for controlling power resources in RK3588. The RK3588 PMU is dedicated for managing the power of the whole chip.
PMU supports the following features:

- Support multi voltage domains: VD_BIGCORE0, VD_BIGCORE1, VD_LITDSU, VD_GPU, VD_NPU, VD_VCODEC, VD_DDR01, VD_DDR23, VD_LOGIC, VD_PMU
- Support multi power domains in VD_BIGCORE0: PD_CPU_4, PD_CPU_5
- Support multi power domains in VD_BIGCORE1: PD_CPU_6, PD_CPU_7
- Support multi power domains in VD_LITDSU: PD_CPU_0, PD_CPU_1, PD_CPU_2, PD_CPU_3
- Support multi power domains in VD_NPU: PD_NPUTOP, PD_NPU1, PD_NPU2
- Support multi power domains in VD_VCODEC: PD_RKVDEC0, PD_RKVDEC1, PD_VENC0, PD_VENC1
- Support multi power domains in VD_LOGIC: PD_VDPU, PD_RGA30, PD_AV1, PD_VI, PD_FEC, PD_ISP1, PD_RGA31, PD_VOP, PD_VO0, PD_VO1, PD_AUDIO, PD_PHP, PD_GMAC, PD_PCIE, PD_NVM, PD_NVM0, PD_SDIO, PD_USB, PD_SECURE, PD_SDMMC, PD_CRYPTO, PD_CENTER, PD_VOP_CLUSTER0, PD_VOP_CLUSTER1, PD_VOP_CLUSTER2, PD_VOP_CLUSTER3, PD_VOP_DSC8K, PD_VOP_DSC4K, PD_VOP_ESMART
- Support one power domain in VD_PMU: PD_PMU1
- Support BIU idle operations: BIU_BIGCORE0, BIU_BIGCORE1, BIU_DSU, BIU_LITDSU, BIU_GPU, BIU_NPUTOP, BIU_NPU1, BIU_NPU2, BIU_VENC0, BIU_VENC1, BIU_RKVDEC0, BIU_RKVDEC1, BIU_VDPU, BIU_AV1, BIU_ISP1, BIU_RGA31, BIU_VOP, BIU_VOP_CHANNEL, BIU_VO0, BIU_VO1, BIU_AUDIO, BIU_NVM, BIU_SDIO, BIU_USB, BIU_PHP, BIU_VO1USBTOP, BIU_SECURE, BIU_SECURE_CENTER_CHANNEL, BIU_SECURE_VO1USB_CHANNEL, BIU_CENTER, BIU_CENTER_CHANNEL, BIU_DDRSCH0, BIU_DDRSCH1, BIU_DDRSCH2, BIU_DDRSCH3, BIU_CENTER_DDRSCH, BIU_BUS, BIU_TOP, BIU_PMU1
- Support CPU auto power down and DSU auto power down
- Support power down/up all power domains by software or hardware
- Support power down/up all voltage domains by software or hardware
- Support to send idle request to BIU
- Support low frequency clock source from PMU_PVTM
- Support PMU clock switch to low frequency clock in low power mode
- Support PLLs power down/up by hardware in low power mode
- Support OSC enable/disable request in low power mode
- Support to clamp all VD_PMU input before power off VD_LOGIC in low power mode
- Support wakeup reset control in power off mode
- Support DDR self-refresh in low power mode
- Support DDR controller clock auto gating in low power mode
- Support varies configurable wakeup source for low power mode
- Support memory repair for all memory in system by software or hardware

## 7.2 Block Diagram

The following figure is the PMU block diagram. The PMU includes the 3 following sections:

- APB Interface and Register: Provide AMBA APB interface for register read and write
- System Power State Control: Provide power management for various low power modes
- Power Gating Control: Provide power gating control for power domains

### 7.3.2 Operation Mode

We define two operation modes of PMU, software power mode and hardware power mode. When operating at software power mode, that means software can manage power sources directly by accessing PMU registers. For example, CPU or MCU_PMU can write PMU_PWR_GATE_CON0/1/2 registers to determine that power off/on which power domain independently.

When operating at hardware power mode, software manages power sources indirectly through FSM (Finite States Machine) in PMU and those settings always not take effect immediately. That means software also can configure PMU registers to power down/up some power resources, but these setting will not be executed immediately after configuration. They will be delayed to execute after FSM running in particular phase. And the specific power sources will be controlled during specific status in FSM. So the low power mode is a "delay affect" way to handle power sources inside the RK3588 chip.

### 7.3.3 Low Power Mode

There are 2 low power modes defined for RK3588: Power mode 0, Power mode 1.

Power mode 0: Ultra low power mode. In this power mode, all logic except ALIVE in VD_PMU0 can be power off or power down. Chip can be waked up by GPIO interrupt triggered by IO in PMUIO1 domain.

Power mode 1: Low power mode. In this power mode, all logic except ALIVE and PD_PMU1 in VD_PMU0 can be power off or power down. Chip can be waked up by GPIO interrupt triggered by IO in PMUIO1 and PMUIO2 domain or other wake up source from PD_PMU1 when in hardware power mode, or wake up by MCU_PMU when in hardware power mode.

## 7.4 Register Description

RK3588 PMU registers are divided into 3 parts for flexible applications:

- Offset = 0x0000~0x3FFF: registers defined in PMU0, in ALIVE of VD_PMU;
- Offset = 0x4000~0x7FFF: registers defined in PMU1, in PD_PMU1;
- Offset = 0x8000~0xBFFF: registers defined in PMU2, in ALIVE of VD_LOGIC.

Rockchip Confidencial

### 7.4.1 Registers Summary

| Name | Offset | Size | Reset Value | Description |
|---|---|---|---|---|
| PMU_PWR_CON0 | 0x0000 | W | 0x00000000 | PMU power control 0 register |

## 7.5 Application Notes

### 7.5.1 Low Power Mode

PMU can work in power mode 1 by setting bit[0] in PMU_PWR_CON1 register. After setting this bit and all CPUs enter standbywfi state, PMU power mode 1 FSM will start to run. In this low power mode, PMU will manage power resources by hardware or software, such as send idle request or resume transfer to specified BIU interface, power down or power up the specified power domain, DDR enters or exits retention mode, shut down or power up PLL, disable or enable oscillator, and so on. All of above are configurable by setting corresponding registers.

PMU can work in power mode 0 by setting bit[0] in PMU_PWR_CON0 register. After setting this bit and PMU enters power mode 1, PMU power mode 0 FSM will start to run. In this low power mode, PMU will manage PD_PMU1 power resource and idle request, manage DDR retention mode, VCCIO retention mode, disable oscillator, etc. All of above are configurable by setting corresponding registers.

There are similar control bits for bit[0]/[1]/[2]/[3]/[10] in PMU_CRU_PWR_CON and bit[5]/[6]/[7]/[14] in PMU_PWR_CON0. If chip is planned to enter power mode 0, these bits in PMU_CRU_PWR_CON are not need to configure since those low power flow are controlled by PMU_PWR_CON0.

### 7.5.2 Nested Power Domain

There are nested power domains in RK3588, denoted by red-frame and black-frame in "RK3588 Voltage Domain and Power Domain Partition": red-frame used for external power domain, black-frame used for internal power domain. For these power domains, external power domain should not be power down before internal power domain power down, external power domain should be power up before internal power domain power up. These domains are shown below.

Table 7-2 Nested Power Domain 1

| Group ID | External Power Domain | Internal Power Domain |
|---|---|---|
| 1 | PD_VENC0 | PD_VENC1 |
| 2 | PD_NPUTOP | PD_NPU1 |
| 3 | | PD_NPU2 |
| 4 | PD_VI | PD_ISP1 |
| 5 | | PD_FEC |
| 6 | PD_VDPU | PD_AV1 |
| 7 | | PD_RGA30 |
| 8 | PD_SECURE | PD_CRYPTO |
| 9 | | PD_SDMMC |
| 10 | PD_NVM | PD_NVM0 |
| 11 | PD_PHP | PD_GMAC |
| 12 | | PD_PCIE |

Rockchip Confidential

| Group ID | External Power Domain | Internal Power Domain |
|---|---|---|
| 13 | PD_VOP | PD_VOPCLUSTER0 |
| 14 | | PD_VOPDSC4K |
| 15 | | PD_VOPDSC8K |
| 16 | | PD_VOPESMART |
| 17 | PD_VOPCLUSTER0 | PD_VOPCLUSTER1 |
| 18 | | PD_VOPCLUSTER2 |
| 19 | | PD_VOPCLUSTER3 |

It should be noted that the internal power domains in PD_VOP are controlled by VOP internal registers. Moreover, if PD_VOP is power down, both internal power domains in PD_VOP and internal power domains in PD_VOPCLUSTER0 are power down meanwhile.
Incorrect power order may cause power leakage.

Moreover, because of the signal relationship, "Level 0 Power Domain" should be power up and corresponding BIU clock is active if any IP in "Level 1 Power Domain" want to work. Details of corresponding BIU clock please refers to CRU chapter.

Table 7-3 Nested Power Domain 2

| Group ID | Level 0 Power Domain | Level 1 Power Domain |
|---|---|---|
| 1 | PD_SECURE | PD_VO1 |
| 2 | | PD_USB |
| 3 | PD_VDPU | PD_RKVDEC0 |
| 4 | | PD_RKVDEC1 |
| 5 | PD_NVM | PD_SDIO |
| 6 | PD_VOP | PD_VO0 |

### 7.5.3 Software Power Down and Power Up flow

In order to power down the power domains which are managed by software correctly, the software should obey the flow bellow.

**1. Software power down flow**

(1) Send BIU idle request if BIU interface exists in specific power domain that you want to power down by configure the corresponding bit in PMU_IDLE_SFTCON0/1/2 register. If BIU interface does not exist, skip this step;
(2) Query PMU_IDLE_ACK_STS0/1 register to wait for the corresponding BIU idle acknowledge state; Query PMU_IDLE_STS0/1 register to wait for the corresponding BIU in idle state. If BIU interface does not exist, skip this step;
(3) Enable power down to the specific power domain by setting corresponding bit to 1 in PMU_PWR_GATE_SFTCON0/1/2 register;
(4) Query PMU_PWR_GATE_STS0/1 register to wait for the specific power domain power down;

**2. Software power up without repair flow**

(1) Enable power up to the specific power domain by setting corresponding bit to 0 in PMU_PWR_GATE_SFTCON0/1/2 register;
(2) Query PMU_PWR_GATE_STS0/1 register to wait for the specific power domain power up;
(3) Send BIU resume request to the BIU in specific power domain that you want to power down by configure the corresponding bit in PMU_IDLE_SFTCON0/1/2 register; If BIU interface does not exist, skip this step;
(4) Query PMU_IDLE_ACK_STS0/1 register to wait for the corresponding BIU idle acknowledge state; Query PMU_IDLE_STS0/1 register to wait for the corresponding BIU in idle state; If BIU interface does not exist, skip this step.

**3. Software power up with hardware repair flow**

(1) Enable memory repair to the specific power domain by setting corresponding bit to 1 in PMU_BISR_CON1/2/3/13 register;
(2) Enable power up to the specific power domain by setting corresponding bit to 0 in PMU_PWR_GATE_SFTCON0/1/2 register;
(3) Query PMU_BISR_STS4/5 register to wait for the specific power domain power up and repair done;
(4) Send BIU request to the BIU in specific power domain that you want to power up by configure the corresponding bit in PMU_IDLE_SFTCON0/1/2 register; If BIU interface

Rockchip Confidential

does not exist, skip this step;
(5) Query PMU_IDLE_ACK_STS0/1 register to wait for the corresponding BIU exiting idle acknowledgement state; Query PMU_IDLE_STS0/1 register to wait for the corresponding BIU exit idle state; If BIU interface does not exist, skip this step.

**4. Software power up with software repair flow**

(1) Enable memory repair to the specific power domain by setting corresponding bit to 1 in PMU_BISR_CON4/5/6/13 register;
(2) Set PMU_BISR_CON0[10] to 1 to select software repair mode;
(3) Enable power up to the specific power domain by setting corresponding bit to 0 in PMU_PWR_GATE_SFTCON0/1/2 register;
(4) Query PMU_PWR_GATE_STS0/1 register to wait for the specific power domain power up;
(5) Disable software repair clock gating by set PMU_BISR_CON0[6] to 0;
(6) Enable software memory repair reset to the specific power domain by setting corresponding bit to 1 in PMU_BISR_CON10/11/12/13 register;
(7) Set PMU_BISR_CON0[9] to 1 to initial repair global reset signal high; wait for some time and then set PMU_BISR_CON0[9] to 0 to set repair global reset signal low; wait for some time and then set PMU_BISR_CON0[9] to 1 to set repair global reset signal high;
(8) Query PMU_BISR_STS0/1 register to wait for the specific power domain repair done;
(9) Enable software repair clock gating by set PMU_BISR_CON0[6] to 1;
(10) Send BIU request to the BIU in specific power domain that you want to power up by configure the corresponding bit in PMU_IDLE_SFTCON0/1/2 register; If BIU interface does not exist, skip this step.
(11) Query PMU_IDLE_ACK_STS0/1 register to wait for the corresponding BIU exiting idle acknowledgement state; Query PMU_IDLE_STS0/1 register to wait for the corresponding BIU exit idle state; If BIU interface does not exist, skip this step.

### 7.5.4 Memory Power Control

In RK3588, memory powers are independent of logic powers in the power domain. These memory powers can be controlled by software independently through setting specified bit in PMU_MEM_PWR_GATE_SFTCON0/1/2. They can be power down to reduce power consumption if these memories are not work.
Moreover, some module's memory powers are independent of power domain's memory power in the power domain. In this case, these memory powers can be controlled by software independently through setting specified bit in PMU_SUBMEM_PWR_GATE_SFTCON0/1/2. They can be power down to reduce power consumption if the module is not work. If these memories are pre-power down before its power domain enters power down flow, the memory power acknowledgement should be bypassed through setting specified bit in PMU_SUBMEM_PWR_ACK_BYPASS_CON0/1/2.

### 7.5.5 Power Management IO Usage

There are independent power supplies for different voltage domain. You can communicate with external PMIC (Power Management Integrated Circuits) through I2C interface, or through IO interface.

There are 6 IOs designed for purpose, corresponding Module Pin names are pmic_sleep_1~ pmic_sleep_6. The IO interface configuration is as below.

Table 7-4 Power Management IO Interface

| Module Pin | Direction | Pin Name | IOMUX Setting |
|---|---|---|---|
| pmic_sleep_1 | O | PMIC_SLEEP1/GPIO0_A2_d | PMU1_IOC_GPIO0A_IOMUX_SEL_L[11:8]=1 |
| pmic_sleep_2 | O | PMIC_SLEEP2/GPIO0_A3_d | PMU1_IOC_GPIO0A_IOMUX_SEL_L[15:12]=1 |
| pmic_sleep_3 | O | PMIC_SLEEP3/GPIO0_C1_d | PMU2_IOC_GPIO0C_IOMUX_SEL_L[7:4]=1 |
| pmic_sleep_4 | O | PMIC_SLEEP4/GPIO0_C2_d | PMU2_IOC_GPIO0C_IOMUX_SEL_L[11:8]=1 |
| pmic_sleep_5 | O | PMIC_SLEEP5/GPIO0_C3_d | PMU2_IOC_GPIO0C_IOMUX_SEL_L[15:12]=1 |
| pmic_sleep_6 | O | PMIC_SLEEP6/PDM0_SDI3_M1/ | PMU2_IOC_GPIO0D_IOMUX_ |

Rockchip Confidential

| Module Pin | Direction | Pin Name | IOMUX Setting |
|---|---|---|---|
| | | GPIO0_D6_d | SEL_H[11:8]=1 |

Each pmic_sleep_i(i=0~6) has multi power off requests and you can only choose one at a time. Detail refers to PMU0_GRF_SOC_CON3 and PMU1_GRF_SOC_CON2.

Each voltage domain can generate one power off request. The voltage domain power off request can be generated as below:

(1) Enable power off control bit: Set corresponding bit to 1 in PMU_VOL_GATE_CON0/1;
(2) Power down internal power domain: If there is power domain included in the voltage domain, the power domain should be power down firstly. Else, skip this step;
(3) Power down voltage domain: Set corresponding bit to 1 in PMU_PWR_GATE_CON0/2 by hardware power gating or set corresponding bit to 1 in PMU_PWR_GATE_SFTCON0/2 by software power gating.

### 7.5.6 Debug Information

The PMU internal power states could be monitored through debug IO.
The IO interface configuration is as below.

Table 7-5 PMU Debug IO Interface

| Module Pin | Direction | Pin Name | IOMUX Setting |
|---|---|---|---|
| pmu_debug | O | SPI2_CLK_M2/SDMMC_PWREN/ PMU_DEBUG/GPIO0_A5_d | PMU1_IOC_GPIO0A_IOMUX_ SEL_H[7:4]=3 |

The PMU internal power states are transmitted in 8-bit UART interface mode. If PMU does not enter power mode 0, the debug information is decoded as below.

Table 7-6 PMU Debug Information Decode Before Enter Power Mode 0

| Decode Value | PMU State | Register Description |
|---|---|---|
| 2 | CPU (one CPU of CPU0~CPU7)power down state | PMU_CLUSTER_POWER_STS1[3:0] or [7:4]=4'h1 |
| 3 | Core (BIGCORE0 or BIGCORE1) transfer idle state | PMU_CLUSTER_POWER_STS1[3:0] or [7:4]=4'h2 |
| 4 | Core (BIGCORE0 or BIGCORE1) power down state | PMU_CLUSTER_POWER_STS1[3:0] or [7:4]=4'h3 |
| 5 | DSU transfer idle state | PMU_CLUSTER_POWER_STS1[11:8]= 4'h1 |
| 6 | DSU power down state | PMU_CLUSTER_POWER_STS1[11:8]= 4'h2 |
| 7 | Q-Channel low power state | PMU_GLB_POWER_STS=4'h3 |
| 8 | Bus low power state | PMU_GLB_POWER_STS=4'h4 |
| 9 | DDR enters self-refresh mode for core-clock state | PMU_DDR_POWER_STS=4'h2 |
| 10 | DDR enters retention mode through RETON/RETOFF state | PMU_DDR_POWER_STS=4'h3 |
| 11 | Power domain power down start state | PMU_PWR_GATE_POWER_STS=3'h1 |
| 12 | Power domain power down running state | PMU_PWR_GATE_POWER_STS=3'h2 |

| 31 | Q-Channel active state | PMU_GLB_POWER_STS=4'hd |
| 32 | DSU wake up state | PMU_CLUSTER_POWER_STS1[11:8]= 4'h4 |
| 33 | DSU power up state | PMU_CLUSTER_POWER_STS1[11:8]= 4'h5 |
| 34 | DSU transfer resume state | PMU_CLUSTER_POWER_STS1[11:8]= 4'h6 |
| 35 | Core wake up state | PMU_CLUSTER_POWER_STS1[3:0] or [7:4]=4'h5 |
| 36 | Core power up state | PMU_CLUSTER_POWER_STS1[3:0] or [7:4]=4'h6 |
| 37 | Core transfer resume state | PMU_CLUSTER_POWER_STS1[3:0] or [7:4]=4'h7 |
| 38 | CPU power up state | PMU_CLUSTER_POWER_STS1[3:0] or [7:4]=4'h8 |
| 39 | DDR enters self-refresh mode for AXI-clock state | PMU_DDR_POWER_STS=4'h1 |
| 40 | DDR enters retention mode through RST_IOV state | PMU_DDR_POWER_STS=4'h4 |
| 41 | DDR exits retention mode through RST_IOV state | PMU_DDR_POWER_STS=4'h6 |
| 42 | DDR exits self-refresh mode for AXI-clock state | PMU_DDR_POWER_STS=4'h9 |

If PMU enters power mode 0, the debug information is decoded as below.

Table 7-7 PMU Debug Information Decode After Enter Power Mode 0

| Decode Value | PMU State |
|---|---|
| 1 | PD_PMU1 bus idle state |
| 2 | PD_PMU1 power down state |
| 3 | Clock low frequency state |
| 4 | Oscillator disable state |
| 5 | Sleep state |
| 6 | Wake up state |
| 7 | Oscillator enable state |
| 8 | Clock high frequency state |
| 9 | PD_PMU1 power up state |
| 10 | PD_PMU1 bus normal state |
| 11 | Wake up reset clear state |
| 12 | DDR exits retention mode through RST_IOV state |
| 13 | DDR exits retention mode through RETON/RETOFF state |

### 7.5.7 System Register

PMU support 8 system registers: PMU_SYS_REG0~PMU_SYS_REG7. These registers are placed on PD_PMU1. Software can use these registers to retain some information which is useful after wakeup from any mode. It is used for any mode when PD_PMU1 is power on.

# Chapter 8 MMU600

## 8.1 Overview

The MMU600 is a System-level Memory Management Unit (SMMU) that translates an input address to an output address. This translation is based on address mapping and memory attribute information that is available in the MMU600 internal registers and translation tables. The MMU600 implements the Arm SMMU architecture version 3.1, SMMUv3.1, as the *Arm® System Memory Management Unit Architecture Specification, SMMU architecture version 3.0 and version 3.1* defines.
The version of MMU600 is r2p2-00rel0. There are two MMU600 instances in RK3588, MMU600_PCIE and MMU600_PHP respectively. Their configurations are shown below:

Table 8-1 MMU600_PCIE Configuration

| Configuration Parameters | Value |
|---|---|
| TOPCFG_NO_OF_TBU | 2 |
| TCUCFG_QTW_ADDR_WIDTH | 48 |
| TCUCFG_QTW_DATA_WIDTH | 128 |
| TCUCFG_XLATE_SLOTS | 64 |
| TCUCFG_PTW_SLOTS | 16 |
| TCUCFG_CTW_SLOTS | 4 |
| TCUCFG_WCS1L0_DEPTH | 64 |
| TCUCFG_WCS1L1_DEPTH | 64 |
| TCUCFG_WCS1L2_DEPTH | 256 |
| TCUCFG_WCS1L3_DEPTH | 256 |
| TCUCFG_WCS2L0_DEPTH | 64 |
| TCUCFG_WCS2L1_DEPTH | 64 |
| TCUCFG_WCS2L2_DEPTH | 256 |
| TCUCFG_WCS2L3_DEPTH | 256 |
| TCUCFG_CC_DEPTH | 64 |

| TBUCFG_LFIFO_DEPTH | 4 |
| TBUCFG_WBUF_DEPTH | 32 |

The MMU600 in RK3588 supports following feature:

- Compliance with the SMMUv3.1 architecture:
  - Support for Stage 1 translation, Stage 2 translation, and Stage 1 followed by stage 2 translation
  - Support for ARMv8 AArch32 and AArch64 translation table formats
  - Support for 4KB, 16KB and 64KB granule sizes in AArch64 format
  - Masters can be stalled while a processor handles translation faults, enabling software support for demand paging
  - Configuration tables in memory can support millions of active translation contexts
  - Queues in memory perform MMU600 management, no requirement to stall a processor when it accesses the MMU600
  - A Performance Monitoring Unit (PMU) in each TBU and TCU that enables MMU600 performance to be investigated
  - Reliability, Serviceability, and Availability (RAS) features for cache corruption detection and correction
- Support for AMBA interfaces, including:
  - AMBA DTI communication between the TCU and TBUs, enabling masters to request translations and implement TBU functionality internally
  - Support for the AMBA Low-Power Interface (LPI) Q-Channel so that standard controllers can control power and clock gating
  - AXI5 WAKEUP signaling on all interfaces, including DTI and APB interfaces
- Support for flexible integration:
  - You can place a configurable number of TBUs close to the masters being translated
  - Communication between TBU and TCU over AXI4-Stream, supported using the supplied DTI interconnect components, or any other AXI4-Stream interconnect
- Support for high-performance translation:
  - Scalable configurable micro TLB and Main TLB (MTLB) in the TBU can reduce the number of translation requests to the TCU
  - MTLB partitioning enable the use of MTLB entries to be managed outside the TBU, improving real-time translation performance
  - Optimization to store all architecturally defined page and block sizes, including contiguous page and block entries, as a single entry in the TBU and TCU TLBs
  - Per-TBU prioritization in the TCU enables high-priority transaction streams to be translated
  - TCU prefetch of translation tables, which can be enabled on a per-context basis, improving translation performance for real-time masters that access memory

Rockchip Confidential

linearly

- Hit-Under-Miss (HUM) support in the TBU enables transactions with different AXI IDs to be propagated out of order, when a translation is available
- TBU detection of multiple transactions that require the same translation so that only one TBU request to the TCU is required
- TCU detection of multiple translations that require the same table in memory so that only one TCU memory request is required
- Multi-level, multi-stage walk caches in the TCU reduce translation cost by performing only part of the table walk process on a miss
- A configurable number of concurrent translations in the TBU and TCU promotes high translation throughput

## 8.2 Block Diagram

The MMU600_PCIE is connected with five PCIe controllers and the MMU600_PHP is connected with USB3/GMAC/SATA controller. The Bridge_PCIe/Bridge_PHP will arbiter requests from various masters under first in first out method. As shown below:

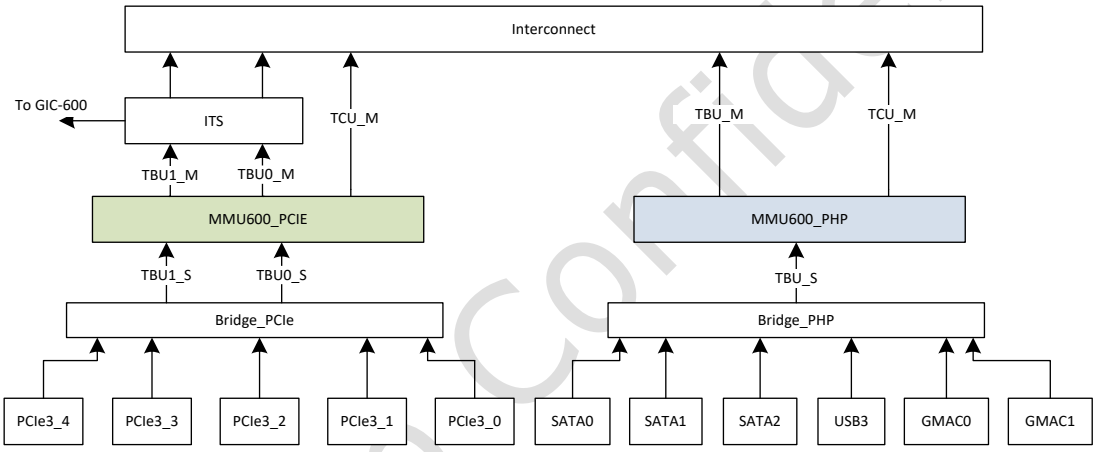

Fig. 8-1 Block Diagram

## 8.3 Function Description

Please refer to the document corelink_mmu600_system_memory_management_unit_technical_reference_manual_100310_0202_00_en.pdf for the detail function description.

# Chapter 9 MCU Subsystem

## 9.1 Overview

The MCU Subsystem embedded one MCU processor(Cortex-M0,r0p0-03rel0), a 16KB unified I/D cache, a tightly-coupled memory(TCM) and interrupt multiplexer(INTMUX). It allowed fast & efficient data exchange. And the Level 1 Instruction/Data Cache designed for MCU can improve the memory access performance significantly.
The following features may or may not be present in the actual product. Please contact Rockchip for the actual feature configurations and the third-party licensing requirements.
The MCU features and benefits are:

- One MCU processor
- Tightly-coupled memory(TCM)
- Optional debug support
  - Two hardware breakpoints
  - One watch points
  - Support Serial Wire debug connection
- Interrupt multiplexer(INTMUX)
  - Mux 8 interrupts from 512 interrupt sources using round-robin algorithm
  - Each 8 adjacent interrupts are seen as a group which share same INTMUX_INT_ENABLE_GROUPx and INTMUX_INT_FLAG_GROUPx register
- 16KB unified I/D Cache
  - Support 2-way set-associative with 32Byte cache line size
  - Support one 128bit AHB-Lite bus master interface to SoC interconnect
  - Support memory cacheable access and peripheral bypass access
  - Support Write-Through with No-Write-Allocate and Read-Allocate
  - Support Write-Back with Write-Allocate and Read-Allocate
  - Support cache maintenance operations (clean/invalidate/clean & invalidate) by address
  - Support cache invalidate/clean & invalidate operations for all cache lines
  - Support cache initialization by software configuration
  - Support RAM debug mode for tag RAM and data RAM
  - Support one interrupt source

There are three MCU subsystem in RK3588, PMU_M0, NPU_M0 and DDR_M0 respectively. Their main configurations are different, As shown below.

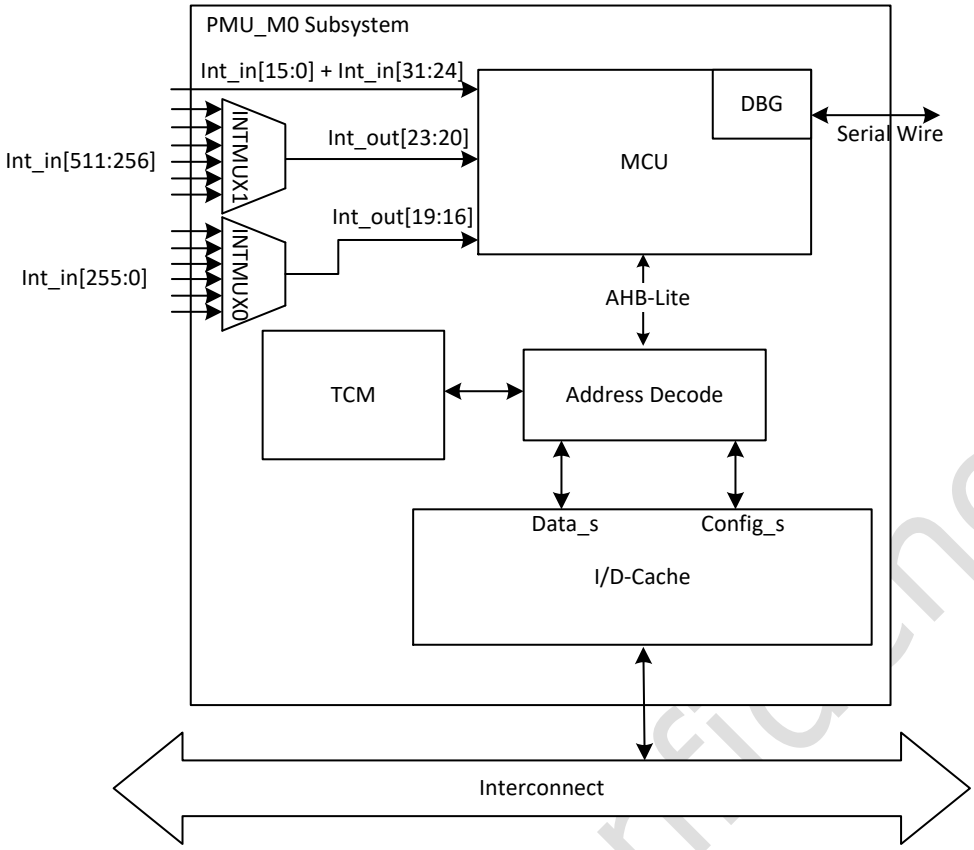
Table 9-1 MCU Subsystem Configurations

| | PMU_M0 | NPU_M0 | DDR_M0 |
|---|---|---|---|
| TCM | 16KB | 64KB | 32KB |
| CACHE | 16KB | 16KB | NA |
| IRQ_NUM | 32 | 16 | 8 |
| INTMUX | YES | NA | YES |

## 9.2 Block Diagram

The Int_in[511:0] will connect with all interrupt source of RK3588, and please refer to "Chapter System Overview" for the detail interrupt number. MCU Subsystem are shown below.

Rockchip Confidential



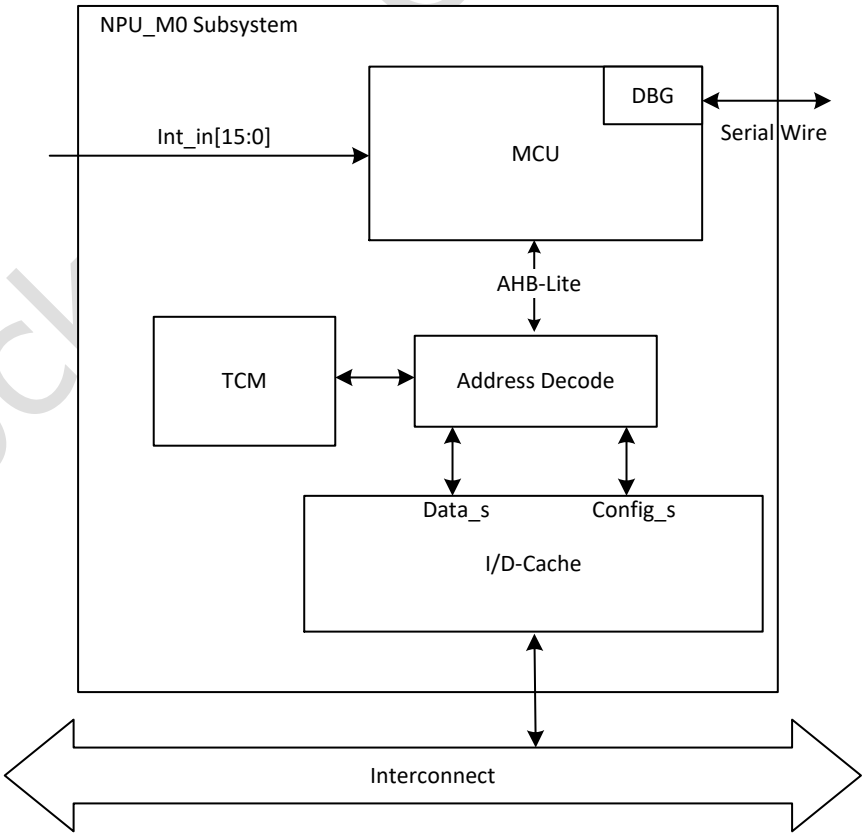


Fig. 9-1 Block Diagram of PMU_M0 Subsystem

Rockchip Confidential

Fig. 9-2 Block Diagram of NPU_M0 Subsystem

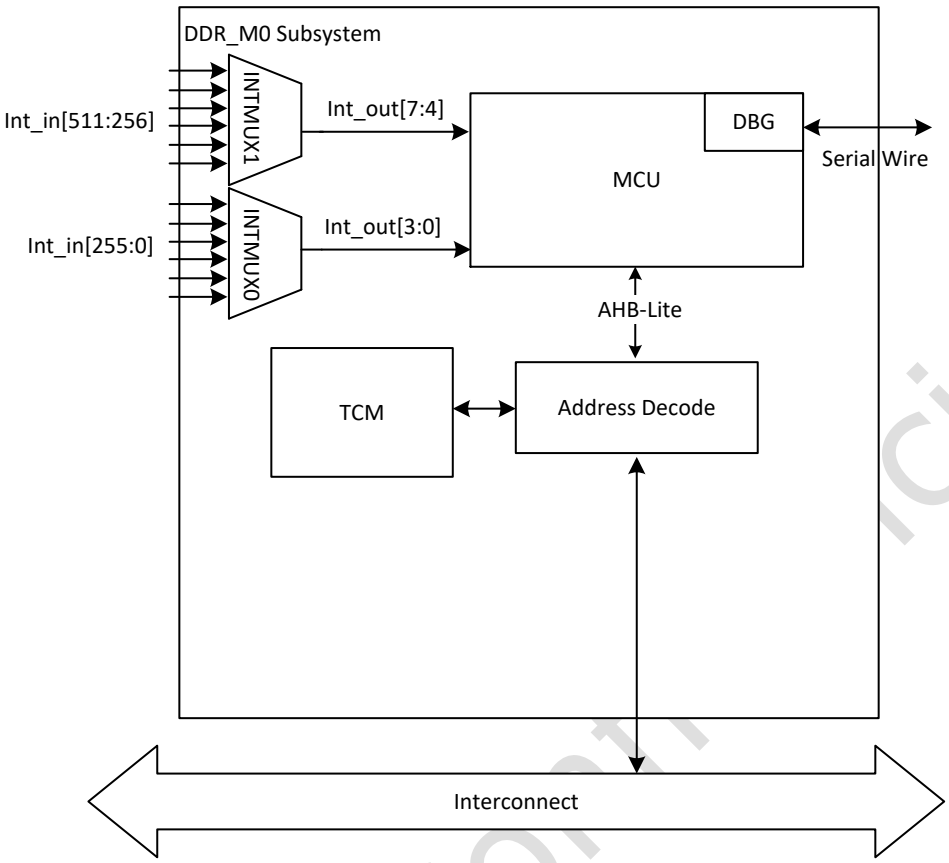

Fig. 9-3 Block Diagram of DDR_M0 Subsystem

## 9.3 Register Description

Software should read and write these registers using 32-bits accesses. Please note that the INTMUX0 and INTMUX1 are same instance, so they have same register list, but the base address of INTMUX0_PMU/INTMUX1_PMU/INTMUX0_DDR/INTMUX1_DDR are 0xFECF0000/0xFECF4000/0xFECF8000/0xFECFC0000 respectively. Every 64 interrupts as a group will be multiplexed into one INT to MCU in order.

### 9.3.1 Registers Summary(cache)

| Name | Offset | Size | Reset Value | Description |
|---|---|---|---|---|
| CACHE_CACHE_CTRL | 0x0000 | W | 0x000006cc | Cache Control Register |
| CACHE_MAINTAIN0 | 0x0004 | W | 0x00000000 | Cache Maintain 0 Register |

## 9.3.4 Detail Registers Description

### INTMUX_INT_ENABLE_GROUP0

Address: Operational Base + offset (0x0000)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:8 | RO | 0x000000 | reserved |
| 7:0 | RW | 0x00 | enable<br>Each bit represents one interrupt enable bit.<br>1'b0: Interrupt disabled<br>1'b1: Interrupt enabled |

### INTMUX_INT_ENABLE_GROUP1

Address: Operational Base + offset (0x0004)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:8 | RO | 0x000000 | reserved |
| 7:0 | RW | 0x00 | enable<br>Each bit represents one interrupt enable bit.<br>1'b0: Interrupt disabled<br>1'b1: Interrupt enabled |

### INTMUX_INT_ENABLE_GROUP2

Address: Operational Base + offset (0x0008)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:8 | RO | 0x000000 | reserved |
| 7:0 | RW | 0x00 | enable<br>Each bit represents one interrupt enable bit.<br>1'b0: Interrupt disabled<br>1'b1: Interrupt enabled |

### INTMUX_INT_ENABLE_GROUP3

Address: Operational Base + offset (0x000c)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:8 | RO | 0x000000 | reserved |
| 7:0 | RW | 0x00 | enable<br>Each bit represents one interrupt enable bit.<br>1'b0: Interrupt disabled<br>1'b1: Interrupt enabled |

### INTMUX_INT_ENABLE_GROUP4

Address: Operational Base + offset (0x0010)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:8 | RO | 0x000000 | reserved |
| 7:0 | RW | 0x00 | enable<br>Each bit represents one interrupt enable bit.<br>1'b0: Interrupt disabled<br>1'b1: Interrupt enabled |

## 9.4 Interface Description

There are two sets of serial debug interface for the three MCUs. When we debug using serial wire, not only set IOMUX, but also configure the bit[11:10] of SYS_GRF_SOC_CON10 to select the MCU that you want to debug.

Rockchip Confidencial

Table 9-2 MCU Serial Wire Debug Interface Description

| Module Pin | Direction | Pad Name | IOMUX Setting |
|---|---|---|---|
| mcujtag_tckm0 | I | SDMMC_CMD/PDM1_CLK1_M0/MCU_JTAG_TCK_M0/CAN0_TX_M1/UART5_RX_M0/PWM7_IR_M1/GPIO4_D4_u | BUS_IOC_GPIO4D_IOMUX_SEL_H[3:0] = 4'h5 |
| mcujtag_tmsm0 | I/O | SDMMC_CLK/PDM1_CLK0_M0/TEST_CLKOUT_M0/MCU_JTAG_TMS_M0/CAN0_RX_M1/UART5_TX_M0/GPIO4_D5_d | BUS_IOC_GPIO4D_IOMUX_SEL_H[7:4] = 4'h5 |
| mcujtag_tckm1 | I | HDMI_TX0_HPD_M1/PCIE30X2_PERSTN_M2/HDMI_RX_HPDOUT_M1/MCU_JTAG_TCK_M1/UART9_RX_M2/SPI0_CS0_M3/GPIO3_D4_d | BUS_IOC_GPIO3D_IOMUX_SEL_H[3:0] = 4'h6 |
| mcujtag_tmsm1 | I/O | PCIE30X4_BUTTON_RSTN/DP1_HPDIN_M0/MCU_JTAG_TMS_M1/UART9_TX_M2/PWM11_IR_M3/SPI0_CS1_M3/GPIO3_D5_d | BUS_IOC_GPIO3D_IOMUX_SEL_H[7:4] = 4'h6 |

*Notes: I=input, O=output, I/O=input/output, bidirectional*

# 9.5 Application Notes

## 9.5.1 Clock and Reset Generation

Please refer to "Chapter CRU" for more detailed information.

## 9.5.2 Memory Remap

The memory map is divided into different memory types for different usage.
To avoid the memory map conflict between different processors, the source space can be remap to another. In addition, these remap operation could not take effect until the MCU soft reset.

Table 9-3 PMU_M0 Address Remap

| Before Remap | Memory Type | Usage | After Remap |
|---|---|---|---|
| 0xA0000000 - 0xDFFFFFFF | Device XN | Peripherals | Before Remap - 0xA0000000 + {pmu1_sgrf_soc_con12[15:0],16'h0} |
| 0x80000000 - 0x9FFFFFFF | Normal WT | Off chip RAM | Before Remap - 0x60000000 + {pmu1_sgrf_soc_con11[15:0],16'h0} |
| 0x60000000 - 0x7FFFFFFF | Normal WBWA | Off chip RAM | Before Remap - 0x60000000 + {pmu1_sgrf_soc_con11[15:0],16'h0} |
| 0x40000000 - 0x5FFFFFFF | Device XN | Peripherals | Before Remap - 0x40000000 + 0xF0000000 |
| 0x20000000 - 0x3FFFFFFF | Normal WBWA | On chip RAM | Before Remap - 0x20000000 + {pmu1_sgrf_soc_con10[15:0],16'h0} |
| 0x00000000 - 0x1FFFFFFF | Normal WT | ROM or flash | Before Remap - 0x0000000 + {pmu1_sgrf_soc_con9[15:0],16'h0} |

Table 9-4 NPU_M0 Address Remap

| Before Remap | Memory Type | Usage | After Remap |
|---|---|---|---|
| 0xA0000000 - 0xDFFFFFFF | Device XN | Peripherals | Before Remap - 0xA0000000 + {bus_sgrf_mcu_con1[15:0],16'h0} |
| 0x80000000 - 0x9FFFFFFF | Normal WT | Off chip RAM | Before Remap - 0x60000000 + {bus_sgrf_mcu_con2[15:0],16'h0} |
| 0x60000000 - 0x7FFFFFFF | Normal WBWA | Off chip RAM | Before Remap - 0x60000000 + {bus_sgrf_mcu_con2[15:0],16'h0} |
| 0x40000000 - 0x5FFFFFFF | Device XN | Peripherals | Before Remap - 0x40000000 + 0xF0000000 |
| 0x20000000 - 0x3FFFFFFF | Normal WBWA | On chip RAM | Before Remap - 0x20000000 + {bus_sgrf_mcu_con3[15:0],16'h0} |
| 0x00000000 - 0x1FFFFFFF | Normal WT | ROM or flash | Before Remap - 0x0000000 + {bus_sgrf_mcu_con0[15:0],16'h0} |

Table 9-5 DDR_M0 Address Remap

| Before Remap | Memory Type | Usage | After Remap |
|---|---|---|---|
| 0xA0000000 - 0xDFFFFFFF | Device XN | Peripherals | Before Remap - 0xA0000000 + {bus_sgrf_mcu_con6[15:0],16'h0} |
| 0x80000000 - 0x9FFFFFFF | Normal WT | Off chip RAM | Before Remap - 0x60000000 + {bus_sgrf_mcu_con7[15:0],16'h0} |

Rockchip Confidential

| | | | |
|---|---|---|---|
| 0x60000000 - 0x7FFFFFFF | Normal WBWA | Off chip RAM | Before Remap - 0x60000000 + {bus_sgrf_mcu_con7[15:0],16'h0} |
| 0x40000000 - 0x5FFFFFFF | Device XN | Peripherals | Before Remap - 0x40000000 + 0xF0000000 |
| 0x20000000 - 0x3FFFFFFF | Normal WBWA | On chip RAM | Before Remap - 0x20000000 + {bus_sgrf_mcu_con8[15:0],16'h0} |
| 0x00000000 - 0x1FFFFFFF | Normal WT | ROM or flash | Before Remap - 0x0000000 + {bus_sgrf_mcu_con5[15:0],16'h0} |

*Notes:*

- XN means execute-never.
- WT means write-through.
- WBWA means write-back-write-allocate.
- WT means write-through

## 9.5.3 Interrupt for MCU

Table 9-6 DDR_M0 Interrupt

| IRQ ID | IRQ Source | IRQ ID | IRQ Source |
|---|---|---|---|
| 0 | Int_in[63:0] | 4 | Int_in[319:256] |
| 1 | Int_in[127:64] | 5 | Int_in[383:320] |
| 2 | Int_in[191:128] | 6 | Int_in[447:384] |
| 3 | Int_in[255:192] | 7 | Int_in[511:448] |

The Int_in[511:0] are system interrupts, and each 64 interrupts will multiplexed into one interrupt which connect to one DDR_M0 IRQ lines. Please refer to "Chapter System Overview" for the detail interrupt number.

Table 9-7 PMU_M0 Interrupt

| IRQ ID | IRQ Source | IRQ ID | IRQ Source |
|---|---|---|---|
| 0 | PMIC | 11 | PWM0 |
| 1 | SDMMC_DETECTN | 12 | WDT_PMU |
| 2 | UART0 | 13 | TIMER1_PMU |
| 3 | GPIO0 | 14 | TIMER0_PMU |
| 4 | GPIO0_EXP | 15 | CRC_CHK_RST_REQ_PMU0_SGRF\| CRC_CHK_RST_REQ_PMU1SGRF |
| 5 | I2C0 | 16-23 | INTMUX_OUT |
| 6 | VAD | 24 | HPTIMER_PMU0 |
| 7 | PDM0 | 25 | OSC_CHK_RST_REQ |
| 8 | I2S1_8CH | 26 | CACHE_PMU |
| 9 | PVTM_PMU | 27-31 | RESERVED |
| 10 | PWM0_PWR | | |

The INTMUX_OUT are multiplexed from 512 system interrupts.

Table 9-8 NPU_M0 Interrupt

| IRQ ID | IRQ Source | IRQ ID | IRQ Source |
|---|---|---|---|
| 0 | Timer0_NPU | 5 | C1_RKNN |
| 1 | Timer1_NPU | 6 | C2_RKNN |
| 2 | PVTM_NPU | 7 | CACHE_NPU |
| 3 | WDT_NPU | 8-11 | MAILBOX2_AP |
| 4 | C0_RKNN | 12-15 | MAILBOX2_BB |

The 16 interrupts are connected to NPU_M0 without INTMUX directly.

## 9.5.4 Cache Initialization

The Cache is bypassed after reset and need to be initialized by the MCU. The basic initialization flow is:

1. Configure to Write-Back or Write-Through mode by setting CACHE_CTRL.cache_wt_en

Rockchip Confidential

and start initialization by configuring CACHE_CTRL.cache_en to high while keeping the Cache in bypass mode (CACHE_CTRL.cache_bypass is high). The store buffer must and only can be enabled for Write-Back mode, so you must disable the store buffer when Write-Through mode is selected. You can also enable the hot buffer for better performance. It is recommended that configure the I-Cache to Write-Through mode and configure the D-Cache to Write-Back mode.

2. Wait for cache initialization to be finished by polling CACHE_STATUS.cache_init_finish.
3. Disable cache bypass mode by configuring CACHE_CTRL.cache_bypass to low. Now that the Cache is enabled.
4. Simply configure CACHE_CTRL.cache_bypass to bypass or enable the Cache again after the initialization flow.

### 9.5.5 Cache Maintenance

The Cache Controller support the following cache maintenance operations:

- Clean by address: push the specified cache line data to external memory if it is valid and dirty.
- Invalidate by address: unconditionally clear the valid and dirty data of the specified cache lines.
- Clean and invalidate by address: clean and then invalidate the specified cache lines.
- Invalidate all: unconditionally clear the valid and dirty data for all the cache lines.
- Clean and invalidate all (Flush): clean and then invalidate all the cache lines.

  For the operation of cache clean and invalidate all, configure CACHE_CTRL.cache_flush to high first, and then wait for flush to be done by polling CACHE_STATUS.cache_flush_done. Finally, if the flush is done, you should configure CACHE_CTRL.cache_flush to low.

For the other four maintenance operations, you should set the maintenance command and the address range of the cache lines by configuring CACHE_MAINTAIN0 and CACHE_MAINTAIN1, then start by configuring CACHE_MAINTAIN0.cache_m_valid to high. When the operation is finished, CACHE_MAINTAIN0.cache_m_valid will be automatically cleared to low. You can also poll CACHE_STATUS.cache_m_busy to judge whether the operation is done.

### 9.5.6 Cache RAM Debug Mode

When the Cache is enabled and not in the bypass mode, you can enter the cache RAM debug mode by configuring CACHE_RAM_DEBUG.ram_debug_en to high. In the RAM debug mode, the cache RAM can be accessed directly by the specific address, and all the other cacheable memory accesses are bypassed because the cache core is disabled.

The following table shows the address map for the cache RAM debug.

Table 9-6 Address Map for the Cache RAM Debug

| RAM Access Type | RAM Access Size | Address Range for Cache RAM Debug |
|---|---|---|
| Reserved | 7KB | 0xF6F26400 ~ 0xF6F27FFF |
| TAG RAM1 | 1KB | 0xF6F26000 ~ 0xF6F263FF |
| Reserved | 7KB | 0xF6F24400 ~ 0xF6F25FFF |
| TAG RAMCU | 1KB | 0xF6F24000 ~ 0xF6F243FF |
| DATA RAM1 | 8KB | 0xF6F22000 ~ 0xF6F23FFF |
| DATA RAMCU | 8KB | 0xF6F20000 ~ 0xF6F21FFF |

As shown in the above table, there are 2 ways for each cache, and the size of one DATA RAM is 8KB. The following explanation may help you use the RAM debug method:

- Using the word-aligned address to access the TAG RAM.
- The bits[9:2] of the TAG RAM address are acted as the bits[12:5] of the corresponding memory address.
- Only the bits[20:0] of the TAG RAM data are available, and the bits[31:21] are always zero.

Rockchip Confidential

  - The bit[20] is the valid flag bit.
  - The bit[19] is the dirty flag bit.
  - The bits[18:0] are acted as the bits[31:13] of the corresponding memory address.
- The bits[12:0] of the DATA RAM address are acted as the bits[12:0] of the corresponding memory address.
- In order to get the cache line data at the wanted address, you should read the both of the TAG RAMs to find the matched address, and then read data from the corresponding DATA RAM.
- If write data to the DATA RAM, 8 copies of the 32bit data on the AHB bus will be written to the 32Byte cache line.

### 9.5.7 TCM

All MCU Subsystem implement data/instructions tightly-coupled memory to speed up code execute, but only MCU can access TCM. In addition, the base address of TCM are configurable to ease software. Refer to pmu1_sgrf_soc_con13/bus_sgrf_mcu_con4/bus_sgrf_mcu_con9 for more detail.

### 9.5.8 Other Hints

One interrupt request source is supported for the I/D-Cache, so you can query the interrupt register in the ISR if it is enabled. When CACHE_INT_EN.err_record_en is high, the Cache will generate a bus error interrupt if access to a wrong address. You can read CACHE_INT_ST.ahb_error_status for the cache interrupt status and get the recent error address information from CACHE_ERR_HADDR.status_haddr.

Rockchip Confidential

# Chapter 10 Timer

## 10.1 Overview

TIMER is a programmable timer peripheral. This component is an APB slave device. In RK3588, there are three types of TIMER according to the count type, which are normal decrement count TIMER, normal increment count TIMER and special function increment count TIMER. The normal decrement count TIMER is called NDCTIMER. The normal increment count TIMER is called NICTIMER. The special function increment count TIMER is called HPTIMER(High Precision TIMER).

5 normal decrement count TIMERs and 1 normal increment count TIMER constitute a 6-channel TIMER. In 6-channel TIMER, TIMER5 is the normal increment count TIMER, and the other channel TIMER is the normal decrement count TIMER.

2 normal increment count TIMERs form a 2-channel TIMER.

HPTIMER has calibration function and provides count value for CPU.

Timer supports the following features:

- All three kinds of counter support 32 bits APB slave.
- All three kinds of counter loading count value support configurable.
- All three kinds of counter support two counting modes: free-running and user-defined count.
- All three kinds of counters support maskable interrupts.
- HPTIMER with three timer mode: Normal, Hardware adjust, Software adjust.
- Hardware adjust mode HPTIMER can be calibrated back to the exact count value without software calculation.
- Software adjust mode HPTIMER can be calibrated back to the exact count value with software-aided calculation.
- Common multiples of slow and fast clock cycles are configurable.

## 10.2 Block Diagram

### 10.2.1 Normal count TIMER block diagram

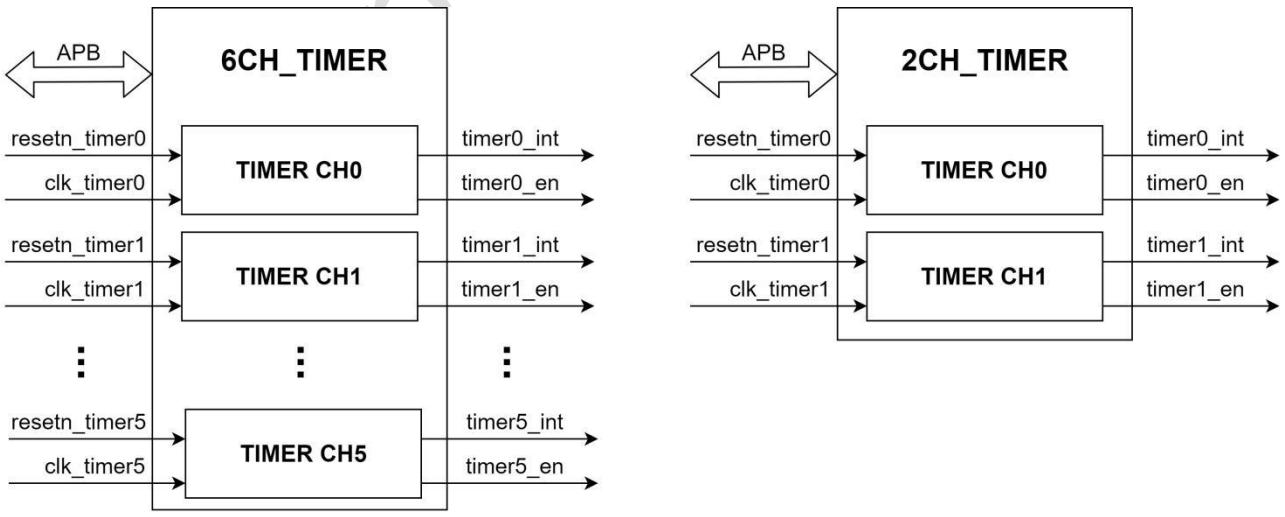

Fig. 10-1 Normal Timer Block Diagram

Fig. 10-1 show 6-channel TIMER and 2-channel TIMER. At 6CH_TIMER, the TIMER ch0~ch4 are the normal decrement count TIMER and ch5 is the normal increment count TIMER. At 2CH_TIMER, ch0 and ch1 are common normal increment count TIMER. APB is the read and write interface of timer register. reset_timern and clk_timern are reset and count clock for each channel timer. Timern_int and timern_en are interrupt and clock enable for each channel timer respectively. (timern is the signal corresponding to TIMER CHn)

Rockchip Confidential

### 10.2.2 HPTIMER block diagram

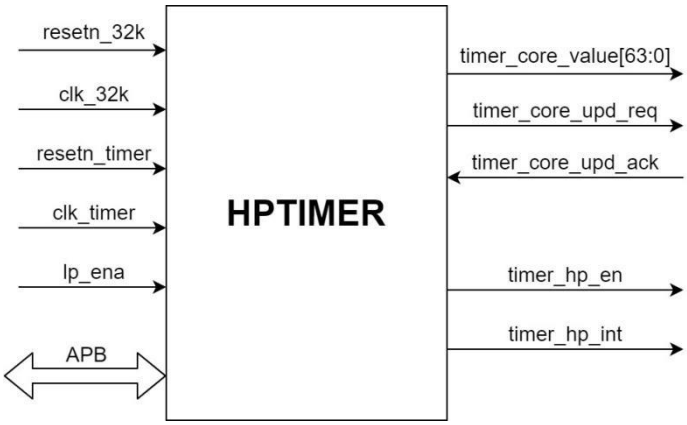

Fig. 10-2 HPTIMER Block Diagram

Fig. 10-2 shows the block diagram of HPTIMER.
HPTIMER has a set of APB interfaces for reading and writing registers.
lp_ena is the low power enable signal sent by PMU to HPTIMER, and it is also the indication signal of clk_timer frequency switching.
timer_core_value[63:0], timer_core_upd_req, timer_core_upd_ack is the interaction signal with core. timer_core_value[63:0] is the count update value, timer_core_upd_req is the update count request signal, timer_core_upd_ack is the update count response signal.
timer_hp_en is the enabling signal of clk_32k and clk_timer clocks. timer_hp_int is the interrupt output of HPTIMER.

## 10.3 Function Description

### 10.3.1 TIMER clock

The clock frequency of the counting clock source of NICTIMER and NDCTIMER is 24MHz. The clock source clock of clk_32k of HPTIMER is 32KHz, and the clock frequency of clk_timer clock source is switched between 24MHz and 32KHz.

### 10.3.2 Programming sequence

#### 10.3.2.1 NDCTIMER and NICTIMER programming sequence

1. Initialize the TIMER by the TIMER_TIMERn_CONTROLREG (0≤n≤5) register:
   1) Disable the timer by writing a "0" to the timer enable bit (bit 0). Accordingly, the timer_en output signal is de-asserted.
   2) Program the timer mode—free-running or user-defined—by writing a "0" or "1" respectively, to the timer mode bit (bit 1).
   3) Set the interrupt mask as either masked or not masked by writing a "0" or "1" respectively, to the timer interrupt mask bit (bit 2).
2. Load the timer count value into the TIMER_TIMERn_LOAD_COUNT1 (0≤n≤5) and TIMER_TIMERn_LOAD_COUNT0 (0≤n≤5) register.
3. Enable the TIMER by writing a "1" to bit 0 of TIMER_TIMERn_CONTROLREG (0≤n≤5).

Rockchip Confidential

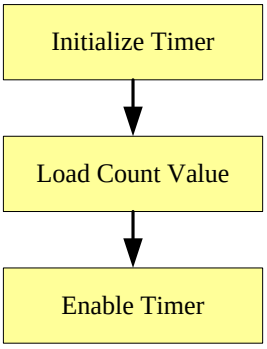

Fig. 10-3 Timer Usage Flow

### 10.3.2.2 HPTIMER programming sequence

- **Normal mode**

1. Initialize the HPTIMER by the TIMER_HP_CTRL register:
   (1) Disable the HPTIMER by writing a '0' to the timer enable bit (bit 0). Accordingly, the timer_hp_en output signal is de-asserted.
   (2) Program the timer mode, normal mode by writing a 0x0 to the timer mode bits (bit 1 to bit 2).
   (3) Program the count mode, free-running or user-defined by writing a '0' or '1' to the count mode bit (bit 3).
2. Load the HPTIMER count value into the TIMER_HP_LOAD_COUNT1 and TIMER_HP_LOAD_COUNT0 register.
3. Enable the HPTIMER by writing a '1' to bit 0 of TIMER_HP_CTRL.

If you want to do another count, repeat steps 1 to 3.

- **Hardware adjust mode**

1. Initialize the HPTIMER by the TIMER_HP_CTRL register:
   (1)Disable the HPTIMER by writing a '0' to the timer enable bit (bit 0). Accordingly, the timer_hp_en output signal is de-asserted.
   (2) Program the timer mode, normal mode by writing a 0x1 to the timer mode bits (bit 1 to bit 2).
   (3) Program the count mode, free-running or user-defined by writing a '0' or '1' to the count mode bit (bit 3).
2. Initialize the HPTIMER by the TIMER_HP_INTR_STATUS register. Write 0x7 to TIMER_HP_INTR_STATUS register to clear TIMER_HP_INTR_STATUS register.
3. Load the HPTIMER count value into the TIMER_HP_LOAD_COUNT1 and TIMER_HP_LOAD_COUNT0 register.
4. Configure the HPTIMER GCD register.
   (1) Divide the least common multiple of clk_timer and clk_32k clock cycle by clk_timer clock cycle and configure it in TIMER_HP_T24_GCD register.
   (2) Divide the least common multiple of clk_timer and clk_32k clock cycle by clk_32k clock cycle and configure it in TIMER_HP_T32_GCD register.
5. Enable the HPTIMER by writing a '1' to bit 0 of TIMER_HP_CTRL.
6. Read out the INTR_STATUS register until the ini_adj_done bit segment (bit 1) is '1', which means that the HPTIMER 32K count is initially adjusted. The low power mode can only be entered after the initial adjustment is completed.
7. The chip enters and exits the low power consumption mode at any time in between.
8. Read out the INTR_STATUS register until the sync_done bit segment (bit 2) is '1', indicating that the HPTIMER count is adjusted.
9. Write 0x7 to TIMER_HP_ INTR_STATUS register to clear TIMER_HP_INTR_STATUS register.

If the chip enters and exits the low power consumption mode again, repeat steps 7 to 9.

- **Software adjust mode**

1. Initialize the HPTIMER by the TIMER_HP_CTRL register:
   (1) Disable the HPTIMER by writing a '0' to the timer enable bit (bit 0). Accordingly, the timer_hp_en output signal is de-asserted.
   (2) Program the timer mode, normal mode by writing a 0x2 to the timer mode bits (bit 1 to bit 2).

Rockchip Confidencial

(3) Program the count mode, free-running or user-defined by writing a '0' or '1' to the count mode bit (bit 3).

2. Initialize the HPTIMER by the TIMER_HP_INTR_STATUS and BEGIN_END_VALID register. Write 0x7 to TIMER_HP_ INTR_STATUS register to clear TIMER_HP_INTR_STATUS register. write 0x3 to BEGIN_END_VALID register to clear BEGIN_END_VALID register.
3. Load the HPTIMER count value into the TIMER_HP_LOAD_COUNT1 and TIMER_HP_LOAD_ COUNT0 register.
4. Enable the HPTIMER by writing a '1' to bit 0 of TIMER_HP_CTRL.
5. The chip enters and exits the low power consumption mode at any time in between.
6. Read out BEGIN_END_VALID register until the value of it is 0x3, which indicates that the chip has entered and exited the low power consumption mode, then you can adjust the timer count value. Then write 0x3 to BEGIN_END_VALID register to clear the register.
7. The count value of HPTIMER compensation.
   (1) Read out TIMER_HP_T24_32BEGIN1, TIMER_ HP_T24_32BEGIN0, TIMER_HP_T32_ 24END1 and TIMER_HP_T32_24END0 register.
   (2) configure TIMER_HP_T24_DELAT_COUNT1 and TIMER_HP_T24_DELAT_COUNT0 registers to compensate for the count values according to the values of these registers read out above.
   (3) Write 0x1 to TIMER_HP_SYNC_REQ register to start compensation counting.
   (4) Read out the INTR_STATUS register until the sync_done bit segment (bit 2) is '1', indicating that the compensation count is completed.
8. Write 0x7 to TIMER_HP_ INTR_STATUS register to clear TIMER_HP_INTR_STATUS register.

If the chip enters and exits the low power consumption mode again, repeat steps 5 to 8.

### 10.3.3 Loading a timer count value

For the descending TIMER(that is, the value from which it counts down). The initial value for each TIMER is loaded into the TIMER using the load count register (TIMER_TIMERn_LOAD_ COUNT1 and TIMER_TIMERn_ LOAD_COUNT0). Two events can cause a TIMER to load the initial value from its load count register:

- TIMER is enabled after reset or disabled.
- TIMER counts down to 0, when TIMER is configured into free-running mode.

For the incremental TIMER(that is, the value from which it counts up). The initial value for each timer is zero. The count register will count up to the value loaded in the register TIMER_ TIMERn_LOAD_COUNT1 and TIMER_TIMERn_ LOAD_COUNT0. Two events can cause a TIMER to load zero:

- TIMER is enabled after reset or disabled.
- TIMER counts up to the value stored in TIMER_TIMERn_LOAD_COUNT1 and TIMER_ TIMERn_LOAD_COUNT0, when timer is configured into free-running mode.

### 10.3.4 Timer mode selection

- User-defined count mode – TIMER loads TIMER_TIMERn_LOAD_COUNT1 and TIMER_ TIMERn_LOAD_ COUNT0 registers (for descending TIMER) or zero (for incremental TIMER) as initial value. When the TIMER counts down to 0 (for descending TIMER) or counts up to the value in TIMER_TIMERn_LOAD_COUNT1 and TIMER_TIMERn_ LOAD_ COUNT0 (for incremental TIMER), it will not automatically reload the count register. User need to disable timer firstly and follow the programming sequence to make timer work again.
- Free-running mode – TIMER loads the TIMER_TIMERn_LOAD_COUNT1 and TIMER_ TIMERn_LOAD_COUNT0(for descending TIMER) or zero(for incremental TIMER) register as initial value. TIMER will automatically reload the count register, when timer counts down to 0(for descending TIMER) or counts up to the value in TIMER_TIMERn_LOAD_ COUNT1 and TIMER_TIMERn_LOAD_COUNT0 (for incremental TIMER).

# 10.4 Register Description

## 10.4.1 Registers Summary

### 10.4.1.1 Normal Count TIMER Register Summary

For 2-channel normal count TIMER, the base address of channel 1 is greater than that of channel 0 by 0x20. For 6-channel normal count TIMER, the base address of channel 1 is greater than that of channel 0 by 0x20, the base address of channel 2 is greater than that of channel 1 by 0x20, and so on. The revision register offset of 2-channel / 6-channel normal count TIMER is 0xf0.
If you want to know that each TIMER is 2-channel or 6-channel, please refer to the "TIMER attributes" section at the end of "Chapter TIMER".

| Name | Offset | Size | Reset Value | Description |
|---|---|---|---|---|
| TIMER_TIMERn_LOAD_COUNT0 | 0x0000 +n*0x20 | W | 0x00000000 | Timern Load Count Register 0 |
| TIMER_TIMERn_LOAD_COUNT1 | 0x0004 +n*0x20 | W | 0x00000000 | Timern Load Count Register 1.Higher 32 bits Value to be loaded into Timer n. This is the value from which counting commences |
| TIMER_TIMERn_CURRENT_VALUE0 | 0x0008 +n*0x20 | W | 0x00000000 | Timern Current Value Register 0 |
| TIMER_TIMERn_CURRENT_VALUE1 | 0x000c +n*0x20 | W | 0x00000000 | Timern Current Value Register 1.High 32 bits of Current Value of Timer n |
| TIMER_TIMERn_CONTROLREG | 0x0010 +n*0x20 | W | 0x00000000 | Timern Control Register |
| TIMER_TIMERn_INTSTATUS | 0x0018 +n*0x20 | W | 0x00000000 | Timern Interrupt Status Register |
| TIMER_2CH_REVISION | 0x00F0 | W | 0x15650302 | 2-channel TIMER version |
| TIMER_6CH_REVISION | 0x00F0 | W | 0x11972006 | 6-channel TIMER version |

*Notes:Size:**B**- Byte (8 bits) access, **HW**- Half WORD (16 bits) access, **W**-WORD (32 bits) access*

### 1.4.1.2 HPTIMER Register Summary

| Name | Offset | Size | Reset Value | Description |
|---|---|---|---|---|
| TIMER_HP_REVISION | 0x0000 | W | 0x13D10201 | HPTIMER version |
| TIMER_HP_CTRL | 0x0004 | W | 0x00000000 | HPTIMER control |
| TIMER_HP_INTR_EN | 0x0008 | W | 0x00000000 | Interrupt musk |
| TIMER_HP_T24_GCD | 0x000C | W | 0x00000000 | Common multiple div 24M |
| TIMER_HP_T32_GCD | 0x0010 | W | 0x00000000 | Common multiple div 32K |
| TIMER_HP_LOAD_COUNT0 | 0x0014 | W | 0x00000000 | Low 32bits of load count value |
| TIMER_HP_LOAD_COUNT1 | 0x0018 | W | 0x00000000 | High 32bits of load count value |
| TIMER_HP_T24_DELAT_COUNT0 | 0x001C | W | 0x00000000 | Low 32bits of 24M clock delay time count value |
| TIMER_HP_T24_DELAT_COUNT1 | 0x0020 | W | 0x00000000 | High 32bits of 24M clock delay time count value |

## 10.5 Application Notes

### 10.5.1 Clock and Enable

In the chip, the timer_clk is from 24MHz XIN_OSC, asynchronous to the pclk. When user disables the timer enables bit (bit 0 of TIMERn_CONTROLREG (0≤n≤5)), the timer en output signal is de-asserted, and timer_clk will stop. When user enables the timer, the timer_en signal is asserted and timer_clk will start running.
The application is only allowed to re-config registers when timer_en is low.

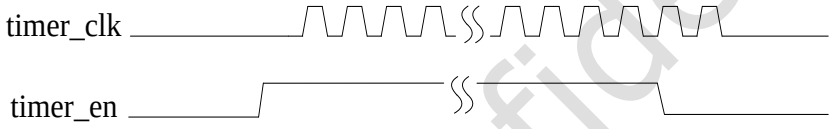

Fig. 10-4 Timing between timer_en and timer_clk

Please refer to function description section for the timer usage flow.

### 10.5.2 HPTIMER application notes

- Initial adjustment, synchronous counting adjustment time is about 2ms.
- When HPTIMER is used as software / hardware adjustment count, the count reaches the TIMER_HP_LOAD_COUNT value, the interrupt status bit will be set, but the count will not stop and continue to count.
- The timer_en of the CTRL register will output as a reference signal for timer clock gating. When timer_en is '0', it will gate the 24M and 32K clocks of the input timer. The application is only allowed to re-config registers when timer_en is low.

### 10.5.3 TIMER attributes

Table 10-1 shows the TIMER name corresponding to each TIMER, the total number of channels and their PD. It also shows the base address of each TIMER, in which the difference of TIMER address offset between adjacent channels in each TIMER is 0x20.

Table 10-1 TIMER attribute

| TIMER Name | CH NUM | PD | Base Address |
|---|---|---|---|
| TIMER_PMU | 2 | pd_pmu1 | 0xfd8f0000 |
| TIMER_NPU | 2 | pd_npu | 0xfdb00000 |
| TIMER_DDR | 2 | pd_center | 0xfe118000 |
| TIMER_S_0 | 6 | pd_secure | 0xfe3d0000 |
| TIMER_S_1 | 6 | pd_bus | 0xfed30000 |
| TIMER_NS_0 | 6 | pd_bus | 0xfeae0000 |
| TIMER_NS_1 | 6 | pd_bus | 0xfeae8000 |
| HP_TIMER | 1 | pd_pmu0 | 0xfd8c8000 |

# Chapter 11 GIC600

## 11.1 Overview

The GIC600 is a generic interrupt controller that handles interrupts from peripherals to the cores and between cores.
The GIC600 supports the GICv3 architecture, refer to the *Arm® Generic Interrupt Controller Architecture Specification, GIC architecture version 3.0 and version 4.0*.
The version of GIC600 is r1p6-00rel0. The configuration of GIC600 is shown below:

Table 11-1 GIC600 Configuration

| Configuration item | Value |
|---|---|
| num_clusters | 1 |
| cpus_per_clsuter_0 | 8 |
| num_spis | 480 |
| disable_security | false |
| lpi_support | true |
| monolithic | 0 |
| ppi_count | 1 |
| its_count | 2 |
| bypass_port | 1 |
| lpi_ram_depth | 128 |
| did_width | 16 |
| vid_width | 16 |
| col_width | 4 |
| axis_rid_width(GICD) | 10 |
| axis_wid_width(GICD) | 10 |
| axim_addr_width(GICD) | 35 |
| axim_data_width(GICD) | 64 |
| axis_addr_width(GICD) | 32 |
| axis_data_width(GICD) | 64 |
| axis_rid_width(ITS) | 8 |
| axis_wid_width(ITS) | 8 |
| axim_addr_width(ITS) | 35 |
| axim_data_width(ITS) | 128 |
| axis_addr_width(ITS) | 35 |
| axis_data_width(ITS) | 128 |

The GIC600 in RK3588 supports following feature:
- Support 1 cluster
- Support cluster 0 with 8 CPUs
- Support 0-32GB address space access by ITS and GICD
- According to the design of SOC, only support Non-shareable attribute of accesses to the LPI tables
- The following interrupt types:
  - Locality-specific Peripheral Interrupts (LPIs). These interrupts are generated by a peripheral writing to a memory-mapped register in the ITS
  - 480 Shared Peripheral Interrupts (SPIs)
  - 12 Private Peripheral Interrupts (PPIs), that are independent for each core and can be programmed to support either edge-triggered or level-sensitive interrupts
  - 16 SGIs, that are generated either by using software to write to GICD_SGIR or through the GIC CPU interface of a core
- Interrupt Translation Service (ITS). This provides device isolation and ID translation for message-based interrupts, which allows virtual machines to program devices directly
- Memory-mapped access to all registers
- Interrupt masking and prioritization
- Programmable interrupt routing that is based on affinity

Rockchip Confidential

- Three different interrupt groups, which allow interrupts to target different Exception levels:
  - Group 0
  - Non-secure Group 1
  - Secure Group 1
- A global Disable Security (DS) bit. This allows support for systems with and without security
- 32 priority values, five bits for each interrupt

## 11.2 Block Diagram

The GIC600 in the RK3588 is connected with CPU cluster through AXI Stream bus. As we can see, ITS is a separate component outside of the Distributor(GICD), since the monolithic configuration is 0. What's more, the GIC Domain and ITS Domain are placed in different power domain which are pd_bus and pd_php power domain respectively. As shown below:

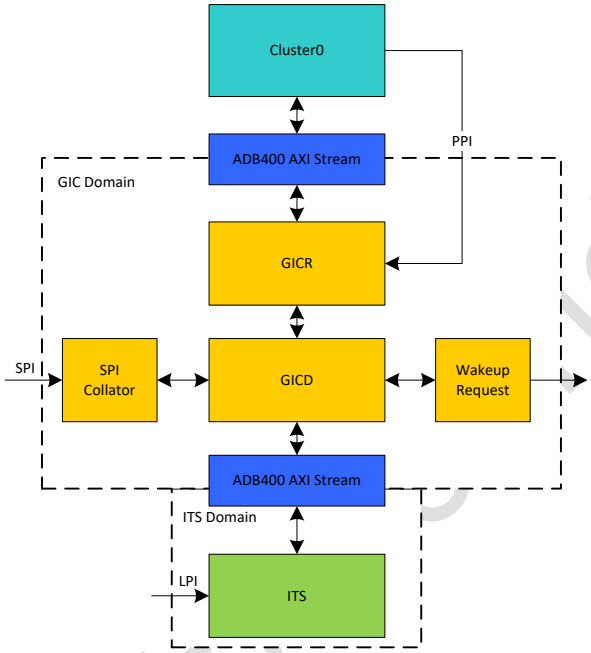

Fig. 11-1 Block Diagram

## 11.3 Function Description

Please refer to the document ARM_GIC-600_r1p6-00rel0_Technical_Reference_Manual.pdf for the detail function description. When we use Q-Channel for clock gating the GIC600 Distributor, remember to configure the bit[1] of SYS_GRF_GIC_CON0 to 1'b0.

Rockchip Confidential

# Chapter 12 DMA Controller (DMAC)

## 12.1 Overview

This device supports 3 Direct Memory Access (DMA) Controller. DMAC0/1/2 support transfers between memory and memory, peripheral and memory. DMAC0/1/2 is under Non-secure state after reset, and the Secure state can be changed by configurable SGRF module.
DMAC supports the following features:

- DMAC0 Supports 24 peripheral requests
- DMAC1 Supports 23 peripheral requests
- DMAC2 Supports 21 peripheral requests
- Up to 64 bits data size
- 8 channel at the same time
- Up to burst 16
- 16 interrupts output and 1 abort output
- Supports 128 MFIFO depth

Following table shows the DMAC request mapping scheme.

Table 12-1 DMAC Request Mapping Table

| DMAC0 | | |
|---|---|---|
| **Req number** | **Source** | **Polarity** |
| 0 | I2S0_8CH_TX | High level |
| 1 | I2S0_8CH_RX | High level |

| 21 | I2S7_8CH_RX | High level |
| 22 | I2S8_8CH_TX | High level |
| 23 | I2S9_8CH_RX | High level |
| 24 | I2S10_8CH_RX | High level |

DMAC supports incrementing-address burst and fixed-address burst. But in the case of access to SPI and UART at byte or half word size, DMAC only supports fixed-address burst and the address must be aligned to word.

## 12.2 Block Diagram

Following figure shows the block diagram of DMAC.

Rockchip Confidential

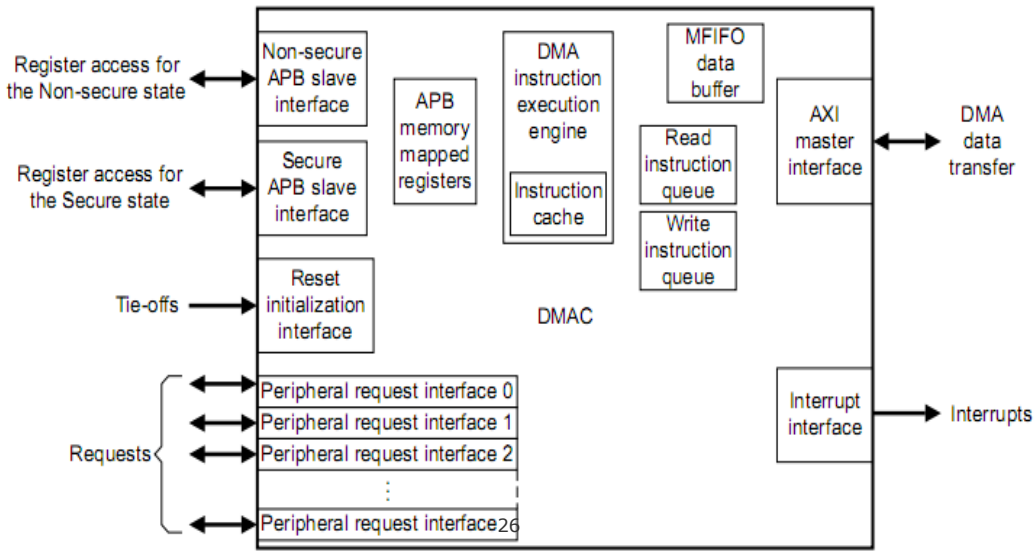

Fig. 12-1 Block Diagram of DMAC

As the DMAC supports TrustZone technology, so dual APB interfaces enable the operation of the DMAC to be partitioned into the Secure state and Non-secure state. You can use the APB interfaces to access status registers and also directly execute instructions in the DMAC. The default interface after reset is Non-secure APB interface.

# 12.3 Function Description

## 12.3.1 Introduction

The DMAC contains an instruction processing block that enables it to process program code that controls a DMA transfer. The program code is stored in a region of system memory that the DMAC accesses using its AXI interface. The DMAC stores instructions temporarily in a cache. It supports 8 channels, each channel capable of supporting a single concurrent thread of DMA operation. In addition, a single DMA manager thread exists, and you can use it to initialize the DMA channel threads. The DMAC executes up to one instruction for each AXI clock cycle. To ensure that it regularly executes each active thread, it alternates by processing the DMA manager thread and then a DMA channel thread. It uses a round-robin process when selecting the next active DMA channel thread to execute.

The DMAC uses variable-length instructions that consist of one to six bytes. It provides a separate Program Counter (PC) register for each DMA channel. When a thread requests an instruction from an address, the cache performs a look-up. If a cache hit occurs, then the cache immediately provides the data. Otherwise, the thread is stalled while the DMAC uses the AXI interface to perform a cache line fill. If an instruction is greater than 4 bytes, or spans the end of a cache line, the DMAC performs multiple cache accesses to fetch the instruction.

When a cache line fill is in progress, the DMAC enables other threads to access the cache, but if another cache miss occurs, this stalls the pipeline until the first line fill is complete. When a DMA channel thread executes a load or store instruction, the DMAC adds the instruction to the relevant read or write queue. The DMAC uses these queues as an instruction storage buffer prior to it issuing the instructions on the AXI bus. The DMAC also contains a Multi First-In-First-Out (MFIFO) data buffer that it uses to store data that it reads, or writes, during a DMA transfer.

## 12.3.2 Operating states

Following figure shows the operating states for the DMA manager thread and DMA channel threads.

Rockchip Confidential

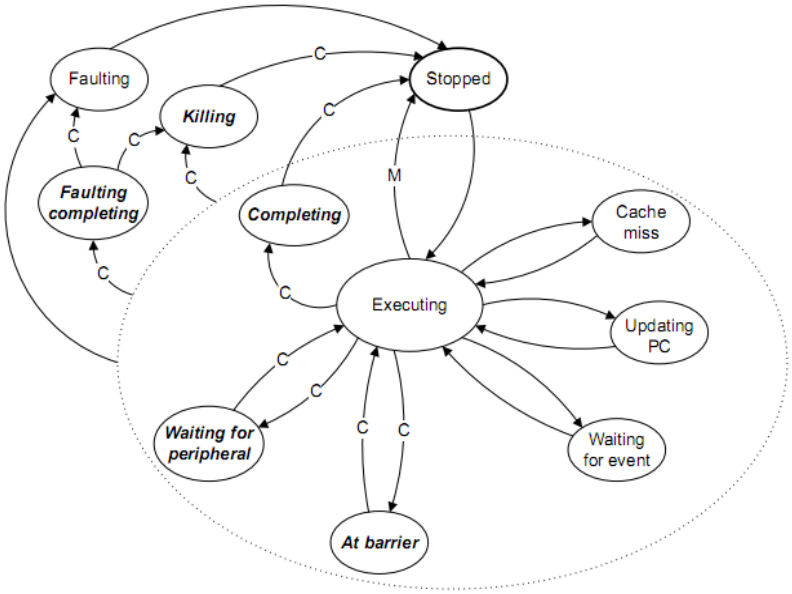

Fig. 12-2 DMAC Operation State

*Notes: arcs with no letter designator indicate state transitions for the DMA manager and DMA channel threads, otherwise use is restricted as follows:*
*C DMA channel threads only.*
*M DMA manager thread only.*

After the DMAC exits from reset, it sets all DMA channel threads to the stopped state, and DMA manager thread moves to the Stopped state.

## 12.4 Register Description

### 12.4.1 Internal Address Mapping

Slave address can be divided into different length for different usage, which is shown as follows.

### 12.4.2 Registers Summary

| Name | Offset | Size | Reset Value | Description |
|---|---|---|---|---|
| DMAC_DSR | 0x0000 | W | 0x00000000 | DMA Manager Status Register |

## 12.5 Timing Diagram

Following picture shows the relationship between dma_req and dma_ack.

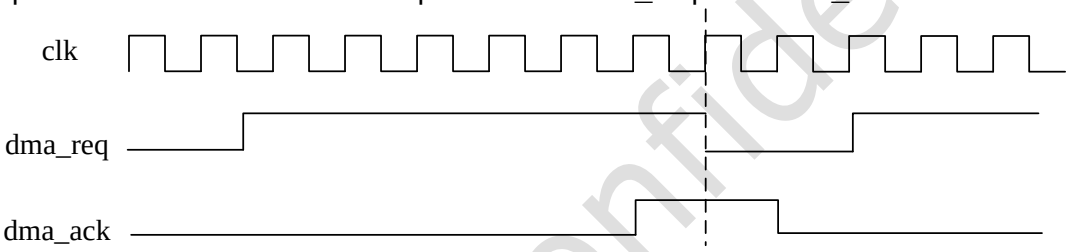

Fig. 12-3 DMAC Request and Acknowledge Timing

## 12.6 Application Notes

### 12.6.1 Using the APB Slave Interfaces

You must ensure that you use the appropriate APB interface, depending on the security state in which the boot_manager_ns initializes the DMAC to operate. For example, if the DMAC is in the secure state, you must issue the instruction using the secure APB interface, otherwise the DMAC ignores the instruction. You can use the secure APB interface, or the non-secure APB interface, to start or restart a DMA channel when the DMAC is in the Non-secure state.

The necessary steps to start a DMA channel thread using the debug instruction registers as following:

1. Create a program for the DMA channel.
2. Store the program in a region of system memory.
3. Poll the DMAC_DBGSTATUS Register to ensure that debug is idle, that is, the dbgstatus bit is 0.
4. Write to the DMAC_DBGINST0 Register and enter the:
- Instruction byte 0 encoding for DMAGO.
- Instruction byte 1 encoding for DMAGO.
- Debug thread bit to 0. This selects the DMA manager thread.

5. Write to the DBGINST1 Register with the DMAGO instruction byte [5:2] data, see Debug Instruction-1 Register o. You must set these four bytes to the address of the first instruction in the program that was written to system memory in step 2.
6. Writing zero to the DMAC_DBGCMD Register. The DMAC starts the DMA channel thread and sets the dbgstatus bit to 1.

### 12.6.2 Security Usage

**DMA manager thread is in the secure state**

If the DNS bit is 0, the DMA manager thread operates in the secure state and it only

Rockchip Confidencial

performs secure instruction fetches. When a DMA manager thread in the secure state processes:

**DMAGO**
It uses the status of the ns bit, to set the security state of the DMA channel thread by writing to the CNS bit for that channel.

**DMAWFE**
It halts execution of the thread until the event occurs. When the event occurs, the DMAC continues execution of the thread, irrespective of the security state of the corresponding INS bit.

**DMASEV**
It sets the corresponding bit in the INT_EVENT_RIS Register, irrespective of the security state of the corresponding INS bit.

**DMA manager thread is in the Non-secure state**
If the DNS bit is 1, the DMA manager thread operates in the Non-secure state, and it only performs non-secure instruction fetches. When a DMA manager thread in the Non-secure state processes:

**DMAGO**
The DMAC uses the status of the ns bit, to control if it starts a DMA channel thread. If:
ns = 0
The DMAC does not start a DMA channel thread and instead it:
1. Executes a NOP.
2. Sets the DMAC_FSRD Register, see Fault Status DMA Manager
3. Sets the dmago_err bit in the DMAC_FTRD Register, see Fault Type DMA Manager Register.
4. Moves the DMA manager to the Faulting state.
ns = 1
The DMAC starts a DMA channel thread in the Non-secure state and programs the CNS bit to be non-secure.

**DMAWFE**
The DMAC uses the status of the corresponding INS bit, in the DMAC_CR3 Register, to control if it waits for the event. If:
INS = 0
The event is in the Secure state. The DMAC:
1. Executes a NOP.
2. Sets the DMAC_FSRD Register, see Fault Status DMA Manager Register.
3. Sets the mgr_evnt_err bit in the DMAC_FTRD Register, see Fault Type DMA Manager Register.
4. Moves the DMA manager to the Faulting state.
INS = 1
The event is in the Non-secure state. The DMAC halts execution of the thread and waits for the event to occur.

**DMASEV**
The DMAC uses the status of the corresponding INS bit, in the CR3Register, to control if it creates the event-interrupt. If:
INS = 0
The event-interrupt resource is in the secure state. The DMAC:
1. Executes a NOP.
2. Sets the DMAC_FSRD Register, see Fault Status DMA Manager Register.
3. Sets the mgr_evnt_err bit in the DMAC_FTRD Register, see Fault Type DMA Manager Register.

Rockchip Confidencial

4. Moves the DMA manager to the Faulting state.
INS = 1
The event-interrupt resource is in the Non-secure state. The DMAC creates the event-interrupt.

**DMA channel thread is in the secure state**
When the CNS bit is 0, the DMA channel thread is programmed to operate in the Secure state and it only performs secure instruction fetches.
When a DMA channel thread in the secure state processes the following instructions:

**DMAWFE**
The DMAC halts execution of the thread until the event occurs. When the event occurs, the DMAC continues execution of the thread, irrespective of the security state of the corresponding INS bit, in the DMAC_CR3 Register.

**DMASEV**
The DMAC creates the event-interrupt, irrespective of the security state of the corresponding INS bit, in the DMAC_CR3 Register.

**DMAWFP**
The DMAC halts execution of the thread until the peripheral signals a DMA request. When this occurs, the DMAC continues execution of the thread, irrespective of the security state of the corresponding PNS bit, in the DMAC_CR4 Register.

**DMALDP, DMASTP**
The DMAC sends a message to the peripheral to communicate that data transfer is complete, irrespective of the security state of the corresponding PNS bit, in the DMAC_CR4 Register.

**DMAFLUSHP**
The DMAC clears the state of the peripheral and sends a message to the peripheral to resend its level status, irrespective of the security state of the corresponding PNS bit, in the DMAC_CR4 Register.
When a DMA channel thread is in the Secure state, it enables the DMAC to perform secure and non-secure AXI accesses.

**DMA channel thread is in the Non-secure state**
When the CNS bit is 1, the DMA channel thread is programmed to operate in the Non-secure state and it only performs non-secure instruction fetches.
When a DMA channel thread in the Non-secure state processes the following instructions:

**DMAWFE**
The DMAC uses the status of the corresponding INS bit, in the DMAC_CR3 Register, to control if it waits for the event. If:
INS = 0
The event is in the Secure state. The DMAC:
1. Executes a NOP.
2. Sets the appropriate bit in the DMAC_FSRC Register that corresponds to the DMA channel number. See Fault Status DMA Channel Register.
3. Sets the ch_evnt_err bit in the DMAC_FTRn(n=0~7) Register, see Fault Type DMA Channel Registers.
4. Moves the DMA channel to the Faulting completing state.
INS = 1
The event is in the Non-secure state. The DMAC halts execution of the thread and waits for the event to occur.

**DMASEV**

Rockchip Confidencial

The DMAC uses the status of the corresponding INS bit, in the DMAC_CR3 Register, to control if it creates the event. If:
INS = 0
The event-interrupt resource is in the Secure state. The DMAC:
1. Executes a NOP.
2. Sets the appropriate bit in the DMAC_FSRC Register that corresponds to the DMA channel number. See Fault Status DMA Channel Register.
3. Sets the ch_evnt_err bit in the DMAC_FTRn(n=0~7) Register, see Fault Type DMA Channel Registers.
4. Moves the DMA channel to the Faulting completing state.
INS = 1
The event-interrupt resource is in the Non-secure state. The DMAC creates the event-interrupt.

**DMAWFP**
The DMAC uses the status of the corresponding PNS bit, in the DMAC_CR4 Register, to control if it waits for the peripheral to signal a request. If:
PNS = 0
The peripheral is in the Secure state. The DMAC:
1. Executes a NOP.
2. Sets the appropriate bit in the DMAC_FSRC Register that corresponds to the DMA channel number. See Fault Status DMA Channel Register.
3. Sets the ch_periph_err bit in the DMAC_FTRn(n=0~7) Register, see Fault Type DMA Channel Registers.
4. Moves the DMA channel to the Faulting completing state.
PNS = 1
The peripheral is in the Non-secure state. The DMAC halts execution of the thread and waits for the peripheral to signal a request.

**DMALDP, DMASTP**
The DMAC uses the status of the corresponding PNS bit, in the DMAC_CR4 Register, to control if it sends an acknowledgement to the peripheral. If:
PNS = 0
The peripheral is in the secure state. The DMAC:
1. Executes a NOP.
2. Sets the appropriate bit in the DMAC_FSRC Register that corresponds to the DMA channel number. See Fault Status DMA Channel Register.
3. Sets the ch_periph_err bit in the DMAC_FTRn(n=0~7) Register, see Fault Type DMA Channel Registers.
4. Moves the DMA channel to the Faulting completing state.
PNS = 1
The peripheral is in the Non-secure state. The DMAC sends a message to the peripheral to communicate when the data transfer is complete.

**DMAFLUSHP**
The DMAC uses the status of the corresponding PNS bit, in the DMAC_CR4 Register, to control if it sends a flush request to the peripheral. If:
PNS = 0
The peripheral is in the secure state. The DMAC:
1. Executes a NOP.
2. Sets the appropriate bit in the DMAC_FSRC Register that corresponds to the DMA channel number. See Fault Status DMA Channel Register.
3. Sets the ch_periph_err bit in the DMAC_FTRn(n=0~7) Register, see Fault Type DMA Channel Registers.
4. Moves the DMA channel to the Faulting completing state.
PNS = 1
The peripheral is in the Non-secure state. The DMAC clears the state of the peripheral and

Rockchip Confidential

sends a message to the peripheral to resend its level status.
When a DMA channel thread is in the Non-secure state, and a DMAMOV CCR instruction attempts to program the channel to perform a secure AXI transaction, the DMAC:
1. Executes a DMANOP.
2. Sets the appropriate bit in the DMAC_FSRC Register that corresponds to the DMA channel number. See Fault Status DMA Channel Register.
3. Sets the ch_rdwr_err bit in the DMAC_FTRn(n=0~7) Register, see Fault Type DMA Channel Registers.
4. Moves the DMA channel thread to the Faulting completing state.

## 12.6.3 Programming Restrictions

**Fixed unaligned bursts**

The DMAC does not support fixed unaligned bursts. If you program the following conditions, the DMAC treats this as a programming error:
Unaligned read

- src_inc field is 0 in the DMAC_CCRn(n=0~7) Register
- the DMAC_SARn(n=0~7) Register contains an address that is not aligned to the size of data that the src_burst_size field contain

Unaligned write

- dst_inc field is 0 in the DMAC_CCRn(n=0~7) Register
- the DMAC_DARn(n=0~7) Register contains an address that is not aligned to the size of data that the dst_burst_size field contains

**Endian swap size restrictions**

If you program the endian_swap_size field in the DMAC_CCRn(n=0~7) Register, to enable a DMA channel to perform an endian swap then you must set the corresponding DMAC_SARn(n=0~7) Register and the corresponding DMAC_DARn(n=0~7) Register to contain an address that is aligned to the value that the endian_swap_size field contains.

**Updating DMA channel control registers during a DMA cycle restrictions**

Prior to the DMAC executing a sequence of DMALD and DMAST instructions, the values you program in to the DMAC_CCRn(n=0~7) Register, DMAC_SARn(n=0~7) Register, and DMAC_DARn(n=0~7) Register control the data byte lane manipulation that the DMAC performs when it transfers the data from the source address to the destination address. You'd better not update these registers during a DMA cycle.

**Resource sharing between DMA channels**

DMA channel programs share the MFIFO data storage resource. You must not start a set of concurrently running DMA channel programs with a resource requirement that exceeds the configured size of the MFIFO. If you exceed this limit then the DMAC might lock up and generate a Watchdog abort.

## 12.6.4 Unaligned Transfers

For a configuration with more than one channel, if any of channels 1 to 7 is performing transfers between certain types of misaligned source and destination addresses, then the output data may be corrupted by the action of channel 0.

Data corruption might occur if all of the following are true:
1. Two beats of AXI read data are received for one of channels 1 to 7.
2. Source and destination address alignments mean that each read data beat is split across two lines in the data buffer (see Splitting data, below).
3. There is one idle cycle between the two read data beats.
4. Channel 0 performs an operation that updates channel control information during this idle cycle (see Updates to channel control information, below).

**Splitting data**

Depending upon the programmed values for the DMA transfer, one beat of read data from

Rockchip Confidencial

the AXI interface need to be split across two lines in the internal data buffer. This occurs when the read data beat contains data bytes which will be written to addresses that wrap around at the AXI interface data width, so that these bytes could not be transferred by a single AXI write data beat of the full interface width.

Most applications of DMA do not split data in this way, so are NOT vulnerable to data corruption from this defect.

The following cases are NOT vulnerable to data corruption because they do not split data:

- Byte lane offset between source and destination addresses is 0 when source and destination addresses have the same byte lane alignment, the offset is 0 and a wrap operation that splits data cannot occur.
- Byte lane offset between source and destination addresses is a multiple of source size.

Table 12-3 Source Size in DMAC_CCRn

| Source size in DMAC_CCRn | Allowed offset between DMAC_SARn and DMAC_DARn |
|---|---|
| SS8 | any offset allowed. |
| SS16 | 0,2,4,6,8,10,12,14 |
| SS32 | 0,4,8,12 |
| SS64 | 0,8 |

### 12.6.5 Interrupt Sharing between Channels

As the DMAC does not record which channel (or list of channels) have asserted an interrupt. So it will depend on your program and whether any of the visible information for that program can be used to determine progress, and help identify the interrupt source.
There are 4 likely information sources that can be used to determine the progress made by a program:
- Program counter (PC)
- Source address
- Destination address
- Loop counters (LC)

For example, a program might emit an interrupt each time that it iterates around a loop. In this case, the interrupt service routine (ISR) would need to store the loop value of each channel when it is called, and then compare against the new value when it is next called. A change in value would indicate that the program has progressed.
The ISR must be carefully written to ensure that no interrupts are lost. The sequence of operations is as follows:
1. Disable interrupts
2. Immediately clear the interrupt in DMA-330
3. Check the relevant registers for both channels to determine which must be serviced
4. Take appropriate action for the channels
5. Re-enable interrupts and exit ISR

### 12.6.6 Instruction Sets

Table 12-4 DMAC Instruction Sets

| Mnemonic | Instruction | Thread Usage |
|---|---|---|
| DMAADDH | Add Halfword | C |
| DMAEND | End | M/C |
| DMAFLUSHP | Flush and notify Peripheral | C |
| DMAGO | Go | M |
| DMAKILL | Kill | C |
| DMALD | Load | C |
| DMALDP | Load Peripheral | C |
| DMALP | Loop | C |
| DMALPEND | Loop End | C |
| DMALPFE | Loop Forever | C |

Rockchip Confidential

| | | |
|---|---|---|
| DMAMOV | Move | C |
| DMANOP | No operation | M/C |
| DMARMB | Read Memory Barrier | C |
| DMASEV | Send Event | M/C |
| DMAST | Store | C |
| DMASTP | Store and notify Peripheral | C |
| DMASTZ | Store Zero | C |
| DMAWFE | Wait For Event M | M/C |
| DMAWFP | Wait For Peripheral | C |
| DMAWMB | Write Memory Barrier | C |
| DMAADNH | Add Negative Halfword | C |

*Notes: Thread usage: C=DMA channel, M=DMA manager*

## 12.6.7 Assembler Directives

In this document, only DMMADNH instruction is took as an example to show the way the instruction assembled. For the other instructions, please refer to pl330_trm.pdf.

**DMAADNH**

Add Negative Halfword adds an immediate negative 16-bit value to the DMAC_SARn(n=0~7) Register or DMAC_DARn(n=0~7) Register, for the DMA channel thread. This enables the DMAC to support 2D DMA operations, or reading or writing an area of memory in a different order to naturally incrementing addresses. See Source Address Registers and Destination Address Registers.

The immediate unsigned 16-bit value is one-extended to 32 bits, to create a value that is the two's complement representation of a negative number between -65536 and -1, before the DMAC adds it to the address using 32-bit addition. The DMAC discards the carry bit so that addresses wrap from 0xFFFFFFFF to 0x00000000. The net effect is to subtract between 65536 and 1 from the current value in the Source or Destination Address Register.

Following table shows the instruction encoding.

Table 12-5 DMAC Instruction Encoding

| | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|
| Imm[15:8] | Imm[7:0] | 0 | 1 | 0 | 1 | 1 | 1 | ra | 0 |

**Assembler syntax**

DMAADNH <address_register>, <16-bit immediate>

where:

<address_register>

Selects the address register to use. It must be either:

SAR

DMAC_SARn(n=0~7) Register and sets ra to 0.

DAR

DMAC_DARn(n=0~7) Register and sets ra to 1.

<16-bit immediate>

The immediate value to be added to the <address_register>.

You should specify the 16-bit immediate as the number that is to be represented in the instruction encoding. For example, DMAADNH DAR, 0xFFF0 causes the value 0xFFFFFFF0 to be added to the current value of the Destination Address Register, effectively subtracting 16 from the DAR.

You can only use this instruction in a DMA channel thread.

# Chapter 13 SDMMC_BUFFER

## 13.1 Overview

The SDMMC_BUFFER is a data buffer, which transfer data from system DMA to chip external through the SDMMC IOs. The following features are supported by SDMMC_BUFFER

- Support 4 bits data out
- Support 1 bit clock out
- Support DMA hardware handshaking interface
- Support AHB Slave interface
- Support 32x32 fifo

## 13.2 Block Diagram

This section provides a description of SDMMC_BUFFER components.

- AHB slave interface
- DATA FIFO
- DATA IO interface

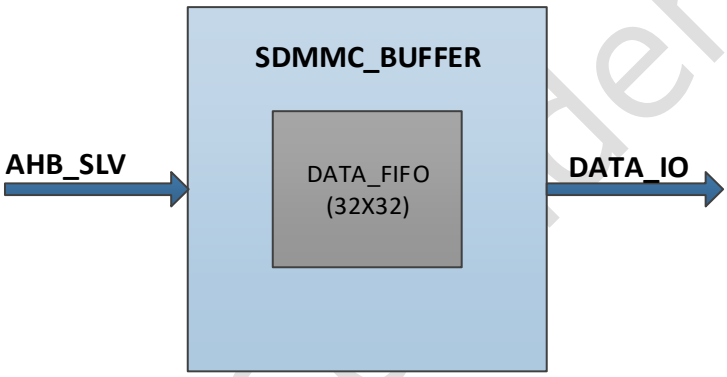

Fig. 13-1 SDMMC_BUFFER Architecture

## 13.3 Function Description

The main block of SDMMC_BUFFER is a 32x32 FIFO, when SDMMC_BUFFER is enable, the DMA handshaking interface is asserted to the system DMA, then the system DMA write data to SDMMC_BUFFER. If the FIFO in SDMMC_BUFFER is not empty, the FIFO data will be transfer to IO

## 13.4 Interface Description

The following table is the interface mapping of between SDMMC_BUF and SDMMC IP.

Table 13-1 SDMMC_BUFFER interface mapping

| SDMMC_BUFFER | SDMMC |
|---|---|
| sdmmc_cclk | sdmmc_cclk |
| sdmmc_cdata0 | sdmmc_cdata0 |
| sdmmc_cdata1 | sdmmc_cdata1 |
| sdmmc_cdata2 | sdmmc_cdata2 |
| sdmmc_cdata3 | sdmmc_cdata3 |

## 13.5 Application Notes

The configuration sequence of enable SDMMC_BUFFER is described as below.

- Set iomux to select sdmmc clock and data io
- Enable IO mux to SDMMC_BUFFER by setting SYS_GRF_SOC_CON10[0]
- Configure write FIFO threshold by setting SYS_GRF_SOC_CON10[7:3]
- Enable SDMMC buffer by setting SYS_GRF_SOC_CON10[1]
- Configure DMA to enable hardware handshaking

# Chapter 14 Temperature-Sensor ADC (TS-ADC)

## 14.1 Overview

TS-ADC Controller is used to control and get the temperature information. TS-ADC will convert for each enable channel in loop after initial setting and can be stopped by software. If you find that the temperature High in a period of time, an interrupt is generated to the processor down-measures taken; if the temperature over a period of time High, the resulting TSHUT gave CRU module, let it reset the entire chip, or via GPIO give PMIC. Also, if you find that the temperature Low in a period of time, an interrupt can be generated.
TS-ADC Controller supports the following features:

- Support to 7 channel TS-ADC (near chip center, A76_0/1, A76_2/3, DSU and A55_0/1/2/3, PD_CENTER, NPU, GPU)
- The temperature for High and Low interrupt can be configurable
- The temperature of system reset can be configurable
- The time interval of temperature detection can be configurable
- When detecting a high temperature, the time interval of temperature detection can be configurable
- High temperature debounce can be configurable
- An interrupt can be generated after TS-ADC converts all setting channel
- -40~125°C temperature range and 1°C temperature resolution

## 14.2 Block Diagram

TS-ADC controller comprises with:

- APB Interface
- TS-ADC control logic

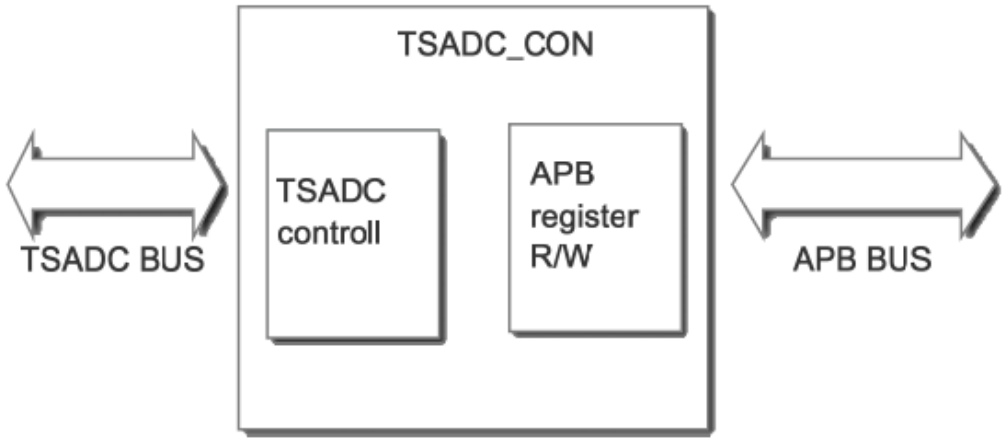

Fig. 14-1 TS-ADC Controller Block Diagram

## 14.3 Function Description

### 14.3.1 APB Interface

There is an APB Slave interface in TS-ADC Controller, which is used to configure the TS-ADC Controller registers and look up the temperature from the temperature sensor.

### 14.3.2 TS-ADC Controller

This block is used to control the TS-ADC PHY to meet the conversion timing and receive the temperature information from TS-ADC PHY.

## 14.4 Register Description

### 14.4.1 Registers Summary

| Name | Offset | Size | Reset Value | Description |
|---|---|---|---|---|
| TSADC_USER_CON | 0x0000 | W | 0x00000000 | User control |
| TSADC_AUTO_CON | 0x0004 | W | 0x00000000 | Auto control |
| TSADC_AUTO_STATUS | 0x0008 | W | 0x00000000 | Status used in auto mode |
| TSADC_AUTO_SRC | 0x000C | W | 0x00000000 | Channel select for TSADC in auto mode |
| TSADC_LT_EN | 0x0010 | W | 0x00000000 | Low temperature check logic enable |
| TSADC_HT_INT_EN | 0x0014 | W | 0x00000000 | High temperature interrupt enable |
| TSADC_GPIO_EN | 0x0018 | W | 0x00000000 | Temperature violation to gpio enable |
| TSADC_CRU_EN | 0x001C | W | 0x00000000 | Temperature violation to cru enable |
| TSADC_LT_INT_EN | 0x0020 | W | 0x00000000 | Low temperature interrupt enable |
| TSADC_HLT_INT_PD | 0x0024 | W | 0x00000000 | High and low temperature interrupt status |
| TSADC_EOC_HSHUT_PD | 0x0028 | W | 0x00000000 | High temperature shut and round int status |
| TSADC_DATA0 | 0x002C | W | 0x00000000 | Channel0 data |
| TSADC_DATA1 | 0x0030 | W | 0x00000000 | Channel1 data |
| TSADC_DATA2 | 0x0034 | W | 0x00000000 | Channel2 data |
| TSADC_DATA3 | 0x0038 | W | 0x00000000 | Channel3 data |
| TSADC_DATA4 | 0x003C | W | 0x00000000 | Channel4 data |
| TSADC_DATA5 | 0x0040 | W | 0x00000000 | Channel5 data |
| TSADC_DATA6 | 0x0044 | W | 0x00000000 | Channel6 data |
| TSADC_DATA7 | 0x0048 | W | 0x00000000 | Channel7 data |
| TSADC_DATA8 | 0x004C | W | 0x00000000 | Channel8 data |
| TSADC_DATA9 | 0x0050 | W | 0x00000000 | Channel9 data |
| TSADC_DATA10 | 0x0054 | W | 0x00000000 | Channel10 data |
| TSADC_DATA11 | 0x0058 | W | 0x00000000 | Channel11 data |
| TSADC_DATA12 | 0x005C | W | 0x00000000 | Channel12 data |
| TSADC_DATA13 | 0x0060 | W | 0x00000000 | Channel13 data |
| TSADC_DATA14 | 0x0064 | W | 0x00000000 | Channel14 data |
| TSADC_DATA15 | 0x0068 | W | 0x00000000 | Channel15 data |
| TSADC_COMP0_INT | 0x006C | W | 0x00000000 | High temperature interrupt threshold for channel0 |
| TSADC_COMP1_INT | 0x0070 | W | 0x00000000 | High temperature interrupt threshold for channel1 |
| TSADC_COMP2_INT | 0x0074 | W | 0x00000000 | High temperature interrupt threshold for channel2 |
| TSADC_COMP3_INT | 0x0078 | W | 0x00000000 | High temperature interrupt threshold for channel3 |
| TSADC_COMP4_INT | 0x007C | W | 0x00000000 | High temperature interrupt threshold for channel4 |
| TSADC_COMP5_INT | 0x0080 | W | 0x00000000 | High temperature interrupt threshold for channel5 |
| TSADC_COMP6_INT | 0x0084 | W | 0x00000000 | High temperature interrupt threshold for channel6 |
| TSADC_COMP7_INT | 0x0088 | W | 0x00000000 | High temperature interrupt threshold for channel7 |

# 14.5 Application Notes

## 14.5.1 Conversion Flow

The system works as following

1) Set the conversion channel in register TSADC_AUTO_SRC, jump channel is not suggested.
2) Temperature violation and other configuration may be set.
3) Set the bit[0] in register TSADC_AUTO_CON, then TS-ADC will work.
4) Then temperature information can be read from APB interface.
5) If TS-ADC needs to be closed, set bit[0] in register TSADC_AUTO_CON to 1'b0.

## 14.5.2 Timing Diagram

When TS-ADC start to work, the timing will follow the Fig.1-2

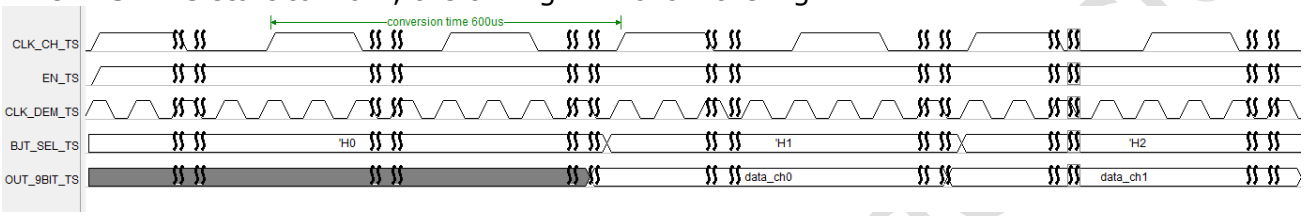

Fig. 14-2 Timing diagram for TS-ADC

When TS-ADC start to work, EN_TS comes to high. Every two CLK_CH_TS cycle, the conversion of one channel is done and channel will change to next one showing as BJT_SEL_TS. Output data from TS-ADC PHY will be kept until next time this channel conversion is done.

CLK_DEM_TS is the main clock for TS-ADC, this clock frequency should be set to 2MHz which can be divided from 24MHz OSC clock. About this please refer to CRU section.

## 14.5.3 Temperature-to-Code Mapping

Table 14-1 Temperature Code Mapping

| Temperature (℃) | ADC Output Data | | |
|---|---|---|---|
| | Min | Typ(Dec) | Max |
| -40 | - | 220 | - |
| 25 | - | 285 | - |
| 85 | - | 345 | - |
| 125 | - | 385 | - |

Note:

Code to Temperature mapping of the Temperature sensor is a linear curve. Any temperature, code falling between to 2 given temperatures can be linearly interpolated.

Code to Temperature mapping should be updated based on silicon results.

Rockchip Confidential

# Chapter 15 Debug

## 15.1 Overview

The chip uses the DAP-LITE2 Technology to support Cortex-A55/Cortex-A76 real-time debug.

### 15.1.1 Features

- Invasive debug with core halted
- SW-DP

### 15.1.2 Debug components address map

The following table shows the debug components address in debug memory map:

| Module | Base Address |
|---|---|
| DAP_ROM | 0x00000 |

## 15.2 Block Diagram

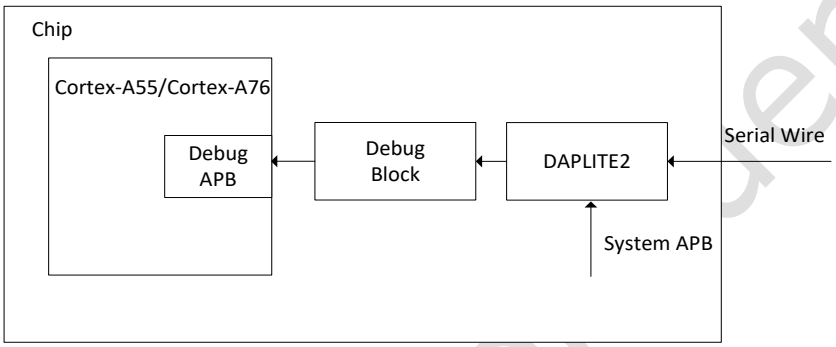

Fig. 15-1 Debug System Structure

## 15.3 Function Description

1.1
2.1
3.1
4.1
5.1

### 15.3.1 DAP

The DAP has following components:

- Serial Wire JTAG Debug Port(SWJ-DP)
- APB Access Port(APB-AP)
- ROM table

The debug port is the host tools interface to access the DAP-Lite2. This interface controls any access ports provided within the DAP-Lite2. The DAP-Lite2 supports a combined debug port which includes both JTAG and Serial Wire Debug(SWD), with a mechanism that supports switching between them.

The APB-AP acts as a bridge between SWJ-DP and APB bus which translate the Debug request to APB bus.

The DAP provides an internal ROM table connected to the master Debug APB port of the APB-Mux. The Debug ROM table is loaded at address 0x00000000 and 0x80000000 of this bus and is accessible from both APB-AP and the system APB input. Bit[31] of the address bus is not connected to the ROM Table, ensuring that both views read the same value. The ROM table stores the locations of the components on the Debug APB.

Please refer to the document CoreSight_DAPLite2_TRM_r0p0.pdf for the debug detail description.

## 15.4 Register Description

Please refer to the document CoreSight_DAPLite2_TRM_r0p0.pdf for the debug detail

description.

# 15.5 Interface Description

## 15.5.1 DAP SWJ-DP Interface

The following figure is the DAP SWJ-DP interface, the SWJ-DP is a combined JTAG-DP and SW-DP that enable you connect either a Serial Wire Debug(SWJ) to JTAG probe to a target.

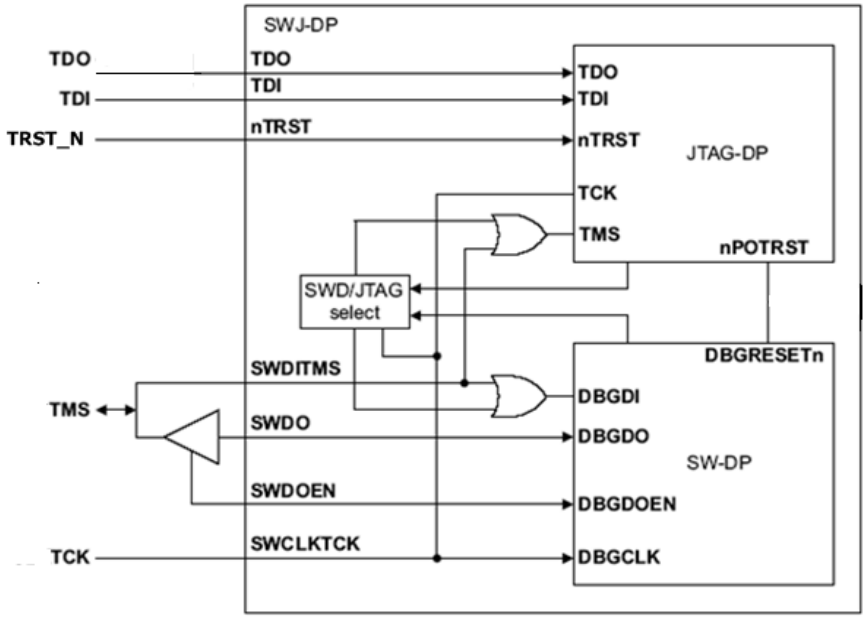

Fig. 15-2 DAP SWJ Interface

## 15.5.2 DAP SW-DP Interface

This implementation is taken from ADIv5.1 and operates with a synchronous serial interface. This uses a single bidirectional data signal, and a clock signal.

The figure below describes the interaction between the timing of transactions on the serial wire interface, and the DAP internal bus transfers. It shows when the target responds with a WAIT acknowledgement.

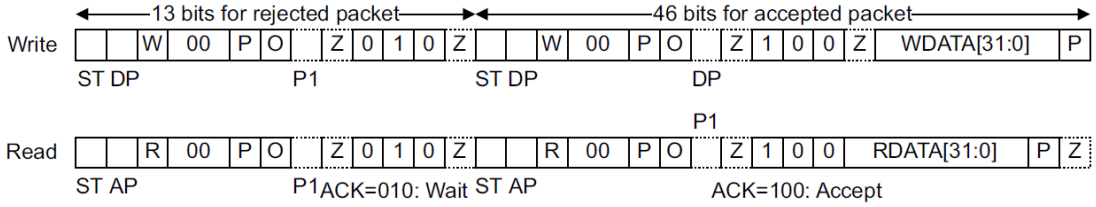

Fig. 15-3 SW-DP Acknowledgement Timing

There are three sets of serial debug interface to debug. By default, jtag_tckm0 and jtag_tmsm0 are connected to corresponding IO pad.

Table 15-1 SW-DP Interface Description

| le pin | Direction | Pad name | IOMUX |
|---|---|---|---|
| jtag_tckm0 | I | SDMMC_D2/PDM1_SDI1_M0/JTAG_TCK_M0/I2C8_SCL_M0/UART5_CTSN_M0/GPIO4_D2_u | BUS_IOC_GPIO4D_IOMUX_SEL_L[11:8]=4'b0101 |

# Chapter 16 Mailbox

## 16.1 Overview

The Mailbox module is a simple APB peripheral that allows CPU, MCU core to communicate with each other by writing operation to generate interrupt. The registers are accessible via APB interface.
There are three mailbox controllers in RK3588.
The Mailbox has the following main features:

- Support APB interface
- Support four mailbox elements, each element includes one data word, one command word register and one flag bit that can represent one interrupt
- Support interrupts to CPU, and MCU core
- Provide 32 lock registers for software to use to indicate whether mailbox is occupied

## 16.2 Block Diagram

The figure below shows Mailbox block diagram:

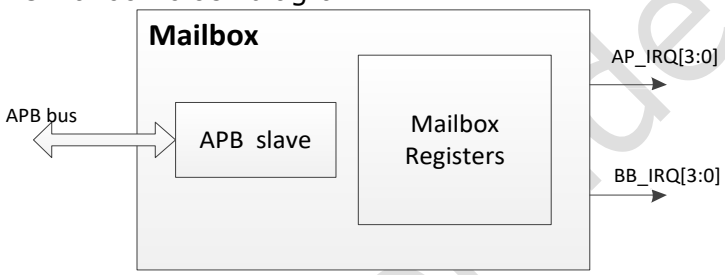

Fig. 16-1 Mailbox Block Diagram

## 16.3 Function Description

### 16.3.1 Mailbox

- Regard CPU as the "AP" side of the Mailbox. The four elements interrupt to CPU is:
  - Enabled when MAILBOX_B2A_INTEN[i] is set to 1 (i=0~3) and the responding IRQs is enabled in GIC.
  - Generated when there are writing operation to corresponding MAILBOX_B2A_CMD_i and MAILBOX_B2A_DAT_i orderly.
  - Cleared when writing 1 to corresponding MAILBOX_B2A_STATUS[i].
- Regard MCU core as the "BB" side of the Mailbox. The four elements interrupt to MCU core is:
  - Enabled when MAILBOX_A2B_INTEN[i] is set to 1 (i=0~3) and the responding IRQs is enabled in INTC of MCU.
  - Generated when there are writing operation to corresponding MAILBOX_A2B_CMD_i and MAILBOX_A2B_DAT_i orderly.
  - Cleared when writing 1 to corresponding MAILBOX_A2B_STATUS[i].
- You can also regard CPU as the "BB" side of the Mailbox and regard MCU core as the "AP" side of the Mailbox. The configuration flow is similar.

## 16.4 Register Description

### 16.4.1 Internal Address Mapping

Slave address can be divided into different length for different usage, which is shown as follows.

### 16.4.2 Registers Summary

| Name | Offset | Size | Reset Value | Description |
|---|---|---|---|---|
| MAILBOX_A2B_INTEN | 0x0000 | W | 0x00000000 | AP to BB Interrupt Enable Register |
| MAILBOX_A2B_STATUS | 0x0004 | W | 0x00000000 | AP to BB Interrupt Status Register |

## 16.5 Application Notes

- It is recommended to read one ATOMIC_LOCK register first when using the Mailbox. The read value is 0 means it is available, and 1 means it has been automatically locked. Writing to the ATOMIC_LOCK register will clear this bit.
- Write to the CMD register before writing to the DAT register. If wrong order is used, then

Rockchip Confidencial

the interrupt cannot be generated successfully.

- If you want to clear the interrupt, you can read out the STATUS register and writing 1 to corresponding bit.
- MAILBOX0 is suggested to use for communication between MCU in PD_PMU and CPU. MAILBOX1 is suggested to use for communication between MCU in PD_CENTER and CPU. MAILBOX2 is suggested to use for communication between MCU in PD_NPU and CPU.

Rockchip Confidencial

# Chapter 17 Watchdog Timer(WDT)

## 17.1 Overview

Watchdog Timer (WDT) is an APB slave peripheral that can be used to prevent system lockup that caused by conflicting parts or programs in a SOC. The WDT would generate interrupt or reset signal when its counter reaches zero, then a reset controller would reset the system.

WDT supports the following features:

- 32 bits APB bus width
- WDT counter's clock can be chosen from 24MHz or 32KHz clock
- 32 bits WDT counter width
- Counter counts down from a preset value to 0 to indicate the occurrence of a timeout
- WDT can perform two types of operations when timeout occurs:
  - Generate a system reset
  - First generate an interrupt and if this is not cleared by the service routine by the time a second timeout occurs then generate a system reset
- Programmable reset pulse length
- Total 16 defined-ranges of main timeout period
- There are five WDTs : WDT_PMU,WDT_NPU,WDT_DDR,WDT_S,WDT_NS
- All the five WDTs can drive CRU to generate global software reset

## 17.2 Block Diagram

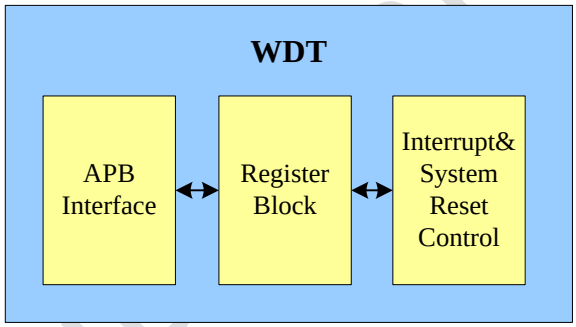

Fig. 17-1 WDT Block Diagram

WDT comprises with:

- APB Interface

The APB Interface implements the APB slave operation. Its data bus width is 32 bits.

- Register Block

A register block that read coherence for the current count register.

- Interrupt & System Reset Control

An interrupt/system reset generation block is comprised of a decrementing counter and control logic.

## 17.3 Function Description

### 17.3.1 Operation

**Counter**

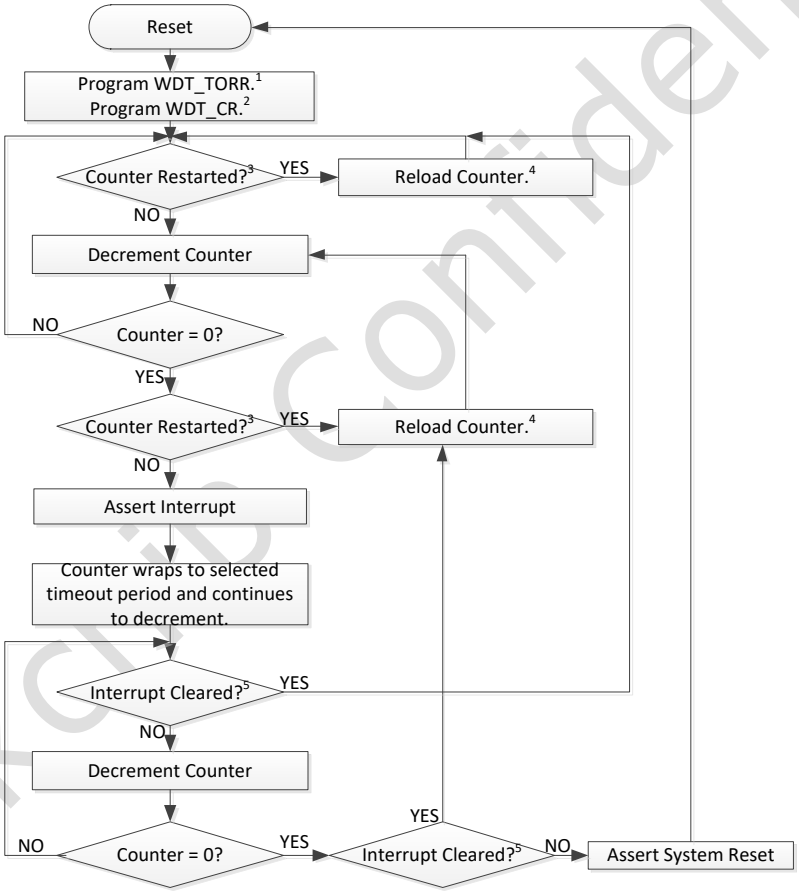
The WDT counts from a preset (timeout) value in descending order to zero. When the counter reaches zero, depending on the output response mode selected, either a system reset or an interrupt occurs. When the counter reaches zero, it wraps to the selected timeout value and continues decrementing. The user can restart the counter to its initial value. This is programmed by writing to the restart register at any time. The process of restarting the watchdog counter is sometimes referred as kicking the dog. As a safety feature to prevent accidental restarts, the value 0x76 must be written to the Current Counter Value Register (WDT_CRR).

Rockchip Confidential

Copyright 2022 © Rockchip Electronics Co., Ltd. 

**Interrupts**

The WDT can be programmed to generate an interrupt (and then a system reset) when a timeout occurs. When a 1 is written to the response mode field (RMOD, bit 1) of the Watchdog Timer Control Register (WDT_CR), the WDT generates an interrupt. If it is not cleared by the time a second timeout occurs, then it generates a system reset. If a restart occurs at the same time the watchdog counter reaches zero, an interrupt is not generated.



**System Resets**

When a 0 is written to the output response mode field (RMOD, bit 1) of the Watchdog Timer Control Register (WDT_CR), the WDT generates a system reset when a timeout occurs.

**Reset Pulse Length**

The reset pulse length is the number of pclk cycles for which a system reset is asserted. When a system reset is generated, it remains asserted for the number of cycles specified by the reset pulse length or until the system is reset. A counter restart has no effect on the system reset once it has been asserted.

### 17.3.2 Programming Sequence

1. Select required timeout period.
2. Set reset pulse length, response mode, and enable WDT.
3. Write 0x76 to WDT_CRR.
4. Starts back to selected timeout period.
5. Can clear by reading WDT_EOI or restarting (kicking) the counter by writing 0x76 to WDT_CRR.

Fig. 17-2 WDT Operation Flow (RMOD=1)

## 17.4 Register Description

This section describes the control/status registers of the design. Software should read and write these registers using 32-bits accesses. There are five WDTs , and each of them has same register group. Therefore, five WDTs' register groups have five different base addresses.

# Chapter 18 Pulse Width Modulation (PWM)

## 18.1 Overview

The pulse-width modulator (PWM) feature is very common in embedded systems. It provides a way to generate a pulse periodic waveform for motor control or can act as a digital-to-analog converter with some external components.
The PWM module supports the following features:

- 4-built-in PWM channels
- Support capture mode
  - Measures the high/low polarity effective cycles of the input waveform
  - Generates a single interrupt at the transition of input waveform polarity
  - 32-bit high polarity capture register
  - 32-bit low polarity capture register
  - 32-bit current value register
  - The capture result can be stored in a FIFO, and the depth of FIFO is 8. The data of FIFO can be read by CPU or DMA
  - Channel 3 support 32-bits power key capture mode
  - Support switch channel IO between channel 3 and channel0/1/2
  - Support a input filter to remove glitch
- Support continuous mode or one-shot mode
  - 32-bit period counter
  - 32-bit duty register
  - 32-bit current value register
  - PWM output polarity in inactive state and duty cycle polarity can be configured
  - Period and duty cycle are shadow buffered. Change takes effect when the end of the effective period is reached or when the channel is disabled
  - Programmable center or left aligned outputs, and change takes effect when the end of the effective period is reached or when the channel is disabled
  - 8-bit repeat counter for one-shot operation. One-shot operation will produce N + 1 periods of the waveform, where N is the repeat counter value, and generates a single interrupt at the end of operation
  - Continuous mode generates the waveform continuously, and does not generates any interrupts
- Support 2 main clock input, one is from crystal oscillator and the frequency is fixed, the other one is from PLL and the frequency can be configured. Each channel can select one of the clocks according to requirement.
- Support two-level frequency division.
- Available low-power mode to reduce power consumption when the channel is inactive.

## 18.2 Block Diagram

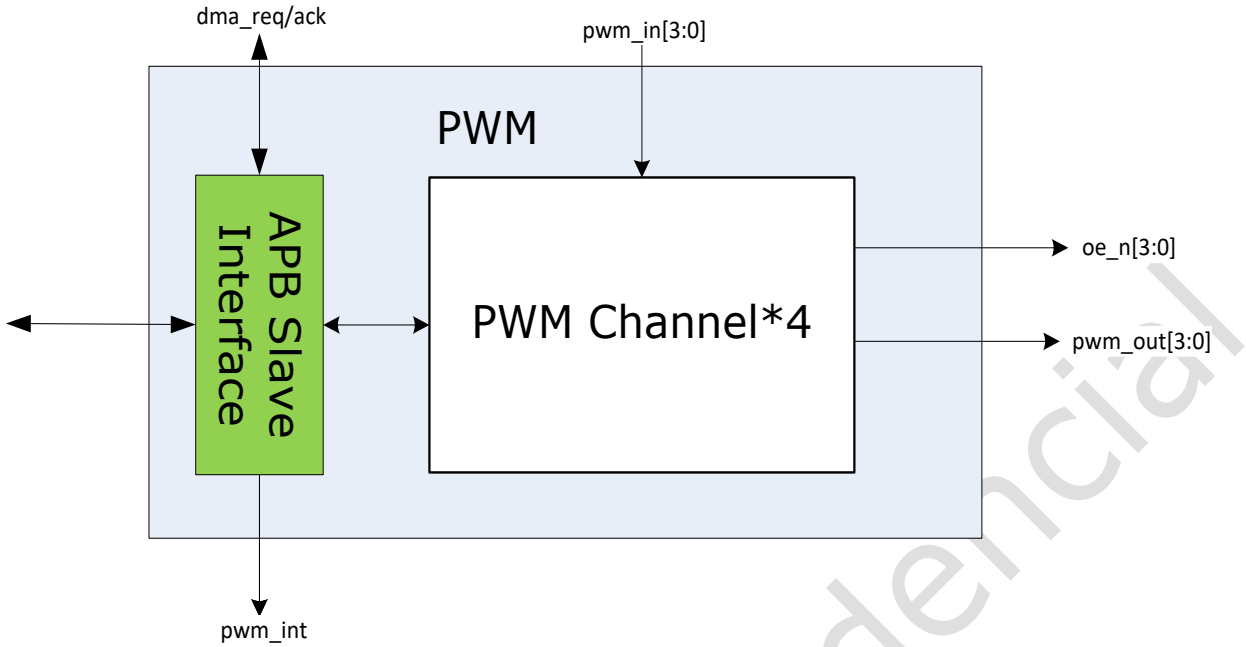

Fig. 18-1 PWM Block Diagram

The host processor gets access to PWM Register Block through the APB slave interface with 32-bit bus width, and asserts the active-high level interrupt. PWM only supports one interrupt output, please refer to interrupt register to know the raw interrupt status when an interrupt is asserted.

PWM Channel is the control logic of PWM module, and controls the operation of PWM module according to the configured working mode.

## 18.3 Function Description

The PWM supports three operation modes: capture mode, one-shot mode and continuous mode. For the one-shot mode and the continuous mode, the PWM output can be configured as the left-aligned mode or the center-aligned mode.

### 18.3.1 Capture mode

The capture mode is used to measure the PWM channel input waveform high/low effective cycles with the PWM channel clock, and asserts an interrupt when the polarity of the input waveform changes. The number of the high effective cycles is recorded in the PWMx_PERIOD_HPC register, while the number of the low effective cycles is recorded in the PWMx_DUTY_LPC register.

*Notes: the PWM input waveform is doubled buffered when the PWM channel is working in order to filter unexpected shot-time polarity transition, and therefore the interrupt is asserted several cycles after the input waveform polarity changes, and so does the change of the values of PWMx_PERIOD_HPC and PWMx_DUTY_LPC.*

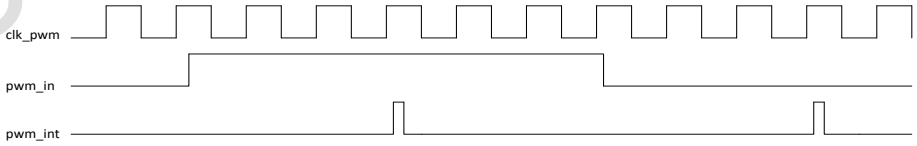

Fig. 18-2 PWM Capture Mode

The capture result can also be stored in a FIFO. The FIFO has an almost full indicator. The indicator can chose to use as an interrupt or DMA request. When it is used as an interrupt, the data in FIFO can be read by CPU. When it is used as a DMA request, the data in FIFO can be read through DMA. It also supports timeout interrupt when the data in FIFO has not been read in a time threshold.

The PWM (only channel 3) support 32-bits power key capture mode. User can configure 10 power key to match, user can poll the status to judge whether a power key access.

Rockchip Confidential

### 18.3.2 Continuous mode

The PWM channel generates a series of the pulses continuously as expected once the channel is enabled with continuous mode.

In the continuous mode, the PWM output waveforms can be in one form of the two output mode: left-aligned mode or center-aligned mode.

For the left-aligned output mode, the PWM channel firstly starts the duty cycle with the configured duty polarity (PWMx_CTRL.duty_pol). Once duty cycle number (PWMx_DUTY_LPC) is reached, the output is switched to the opposite polarity. After the period number (PWMx_PERIOD_HPC) is reached, the output is again switched to the opposite polarity to start another period of desired pulse.

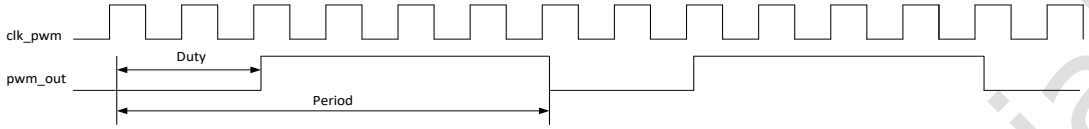

Fig. 18-3 PWM Continuous Left-aligned Output Mode

For the center-aligned output mode, the PWM channel firstly starts the duty cycle with the configured duty polarity (PWMx_CTRL.duty_pol). Once one half of duty cycle number (PWMx_DUTY_LPC) is reached, the output is switched to the opposite polarity. Then if there is one half of duty cycle left for the whole period, the output is again switched to the opposite polarity. Finally after the period number (PWMx_PERIOD_HPC) is reached, the output starts another period of desired pulse.

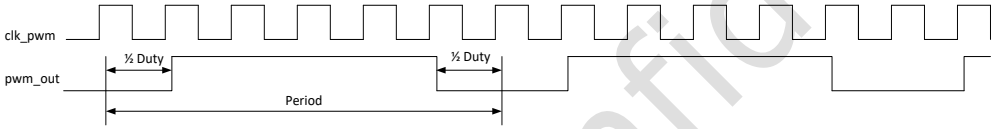

Fig. 18-4 PWM Continuous Center-aligned Output Mode

Once disable the PWM channel, the channel stops generating the output waveforms and output polarity is fixed as the configured inactive polarity (PWMx_CTRL.inactive_pol).

### 18.3.3 One-shot mode

Unlike the continuous mode, the PWM channel generates the output waveforms within the configured periods (PWM_CTRL.rpt + 1), and then stops. At the same times, an interrupt is asserted to inform that the operation has been finished.

There are also two output modes for the one-shot mode: the left-aligned mode and the center-aligned mode.

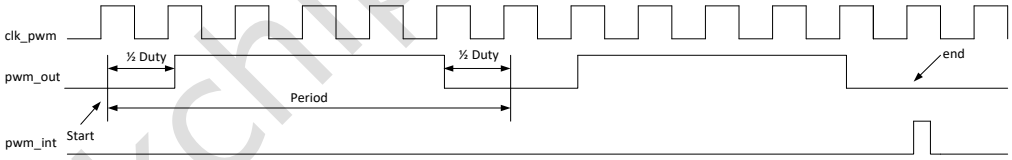

Fig. 18-5 PWM One-shot Center-aligned Output Mode

## 18.4 Register Description

# 18.6 Application Notes

## 18.6.1 PWM Capture Mode Standard Usage Flow

1. Set PWM_PWMx_CTRL.pwm_en to '0' to disable the PWM channel.
2. Choose the prescale factor and the scale factor for clk_pwm by programming PWM_PWMx_CTRL.prescale and PWM_PWMx_CTRL.scale, and select the clock needed by setting PWM_PWMx_CTRL.clk_sel and PWM_PWMx_CTRL.clk_src_sel.
3. Configure the channel to work in the capture mode.
4. Enable the PWM_INT_EN.chx_int_en to enable the interrupt generation.
5. Set PWM_CHANNEL_IO_CTRL. filter_number, then Enable the PWM_CHANNEL_IO_CTRL. CHx_input_filter_enable(Optional).
6. Enable the channel by writing '1' to PWM_PWMx_CTRL.pwm_en bit to start the channel.
7. When an interrupt is asserted, refer to INTSTS register to know the raw interrupt status. If the corresponding polarity flag is set, turn to PWM_PWMx_PERIOD_HPC register to know

Rockchip Confidential

the effective high cycles of input waveforms, otherwise turn to PWM_PWMx_DUTY_LPC register to know the effective low cycles.
8. Write '0' to PWM_PWMx_CTRL.pwm_en to disable the channel.

### 18.6.2 PWM Capture DMA Mode Standard Usage Flow

1. Set PWM_PWMx_CTRL.pwm_en to '0' to disable the PWM channel.
2. Choose the prescale factor and the scale factor for clk_pwm by programming PWM_PWMx_CTRL.prescale and PWM_PWMx_CTRL.scale, and select the clock needed by setting PWM_PWMx_CTRL.clk_sel and PWM_PWMx_CTRL.clk_src_sel.
3. Configure the channel 3 to work in the capture mode.
4. Configure the PWM_FIFO_CTRL.dma_mode_en and PWM_FIFO_CTRL.fifo_mode_sel to enable the DMA mode. Configure PWM_FIFO_CTRL.almost_full_watermark at appropriate value.
5. Configure DMAC_BUS to transfer data from PWM to DDR.
6. Set PWM_CHANNEL_IO_CTRL.filter_number, then Enable the PWM_CHANNEL_IO_CTRL. CHx_input_filter_enable(Optional).
7. Enable the channel by writing '1' to PWM_PWMx_CTRL.pwm_en bit to start the channel.
8. When a dma_req is asserted, DMAC_BUS transfer the data of effective high cycles and low cycles of input waveforms to DDR.
9. Write '0' to PWM_PWMx_CTRL.pwm_en to disable the channel.

### 18.6.3 PWM Power key Capture Mode Standard Usage Flow

1. Set PWM_PWM3_CTRL.pwm_en to '0' to disable the PWM channel.
2. Choose the prescale factor and the scale factor for clk_pwm by programming PWM_PWM3_CTRL.prescale and PWM_PWM3_CTRL.scale, and select the clock needed by setting PWM_PWM3_CTRL.clk_sel. The clock should be 1 MHz after division.
3. Configure the channel to work in the capture mode.
4. Enable the PWM_INT_EN.CH3_int_pwr to enable the interrupt generation.
5. Set the PWM_PWRMATCH_VALUE0~9 registers for the 10 power key match value.
6. Set max_cnt and min_cnt of follow register: PWM_PWRMATCH_LPRE, PWM_PWRMATCH_HPRE, PWM_PWRMATCH_LD, PWM_PWRMATCH_HD_ZERO, PWM_PWRMATCH_HD_ONE. It doesn't need to set these registers when the default value can meet the requirement.
7.Set PWM_PWRMATCH_CTRL.CH3_pwrkey_polarity for the polarity of power key signal, the default value is 0. Enable the PWM_PWRMATCH_CTRL.CH3_pwrkey_enable.
8. Set PWM_CHANNEL_IO_CTRL.filter_number, then Enable the PWM_CHANNEL_IO_CTRL. CH3_input_filter_enable(Optional).
9. Enable the channel by writing '1' to PWM_PWM3_CTRL.pwm_en bit to start the channel.
10. Poll INTSTS. CH3_pwr_IntSts ==1, and refer to PWM_PWM3_PWRCAPTURE_VALUE to know the power key capture value.
11. Write '0' to PWM_PWM3_CTRL.pwm_en to disable the channel.

### 18.6.4 PWM One-shot Mode/Continuous Standard Usage Flow

1. Set PWM_PWMx_CTRL.pwm_en to '0' to disable the PWM channel.
2. Choose the prescale factor and the scale factor for pclk by programming PWM_PWMx_CTRL.prescale and PWM_PWMx_CTRL.scale, and select the clock needed by setting PWM_PWMx_CTRL.clk_sel.
3. Choose the output mode by setting PWM_PWMx_CTRL.output_mode, and set the duty polarity and inactive polarity by programming PWM_PWMx_CTRL.duty_pol and PWM_PWMx_CTRL.inactive_pol.
4. Set the PWM_PWMx_CTRL.rpt if the channel is desired to work in the one-shot mode.
5. Configure the channel to work in the one-shot mode or the continuous mode.
6. Enable the PWM_INT_EN.chx_int_en to enable the interrupt generation if the channel is desired to work in the one-shot mode.
7. If the channel is working in the one-shot mode, an interrupt is asserted after the end of operation, and the PWM_PWMx_CTRL.pwm_en is automatically cleared. Whatever mode the channel is working in, write '0' to PWM_PWMx_CTRL.pwm_en bit to disable the PWM channel.

Rockchip Confidential

### 18.6.5 Low-power Usage Flow

The default value of PWM_PWMx_CTRL.force_clk_en is '0' which make the channel enter the low-power mode. In low-power mode, When the PWM channel is inactive, the clk_pwm to the clock prescale module is gated in order to reduce the power consumption. User can set PWM_PWMx_CTRL.force_clk_en to '1' which will make the channel quit the low-power mode. After the setting, the clk_pwm to the clock prescale module is always enable.

### 18.6.6 Other notes

When the channel is active to produce waveforms, it is free to program the PWM_PWMx_PERIOD_HPC and PWM_PWMx_DUTY_LPC register. User can use PWM_PWMx_CTRL.conlock to take period and duty effect at the same time. The usage flow is as follow:

1. Set PWM_PWMx_CTRL.conlock to '1'.
2. Set PWM_PWMx_PERIOD_HPC and PWM_PWMx_DUTY_LPC.
3. Set PWM_PWMx_CTRL.conlock to '0', others bits in PWM_PWMx_CTRL should be appropriate.

After above configuration, the change will not take effect immediately until the current period ends.

An active channel can be changed to another operation mode without disable the PWM channel. However, during the transition of the operation mode there may be some irregular output waveforms. So does changing the clock division factor when the channel is active.

# Chapter 19 UART

## 19.1 Overview

The Universal Asynchronous Receiver/Transmitter (UART) is used for serial communication with a peripheral, modem (data carrier equipment, DCE) or data set. Data is written from a master (CPU) over the APB bus to the UART and it is converted to serial form and transmitted to the destination device. Serial data is also received by the UART and stored for the master (CPU) to read back.

UART Controller supports the following features:

- Support 10 independent UART controller: UART0-UART9
- All contain two 64 Bytes FIFOs for data receive and transmit
- All support auto flow-control
- Support bit rates 115.2Kbps, 460.8Kbps, 921.6Kbps, 1.5Mbps, 3Mbps, 4Mbps
- Support programmable baud rates, even with non-integer clock divider
- Standard asynchronous communication bits (start, stop and parity)
- Support interrupt-based or DMA-based mode
- Support 5-8 bits width transfer

## 19.2 Block Diagram

This section provides a description about the functions and behavior under various conditions. The UART Controller comprises with:

- AMBA APB interface
- FIFO controllers
- Register block
- Modem synchronization block and baud clock generation block
- Serial receiver and serial transmitter

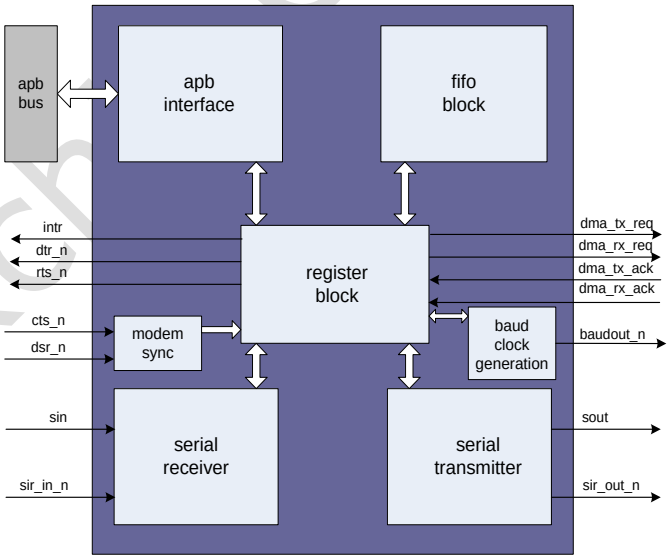

Fig. 19-1 UART Architecture

**APB INTERFACE**

The host processor accesses data, control, and status information on the UART through the APB interface. The UART supports APB data bus widths of 8, 16, and 32 bits.

**Register block**

Be responsible for the main UART functionality including control, status and interrupt generation.

Rockchip Confidential

**Modem Synchronization block**
Synchronizes the modem input signal.

**FIFO block**
Be responsible for FIFO control and storage (when using internal RAM) or signaling to control external RAM (when used).

**Baud Clock Generator**
Generates the transmitter and receiver baud clock along with the output reference clock signal (baudout_n).

**Serial Transmitter**
Converts the parallel data, written to the UART, into serial form and adds all additional bits, as specified by the control register, for transmission.

**Serial Receiver**
Converts the serial data character (as specified by the control register) received to parallel form. Parity error detection, framing error detection and line break detection is carried out in this block.

## 19.3 Function Description

**UART (RS232) Serial Protocol**
Because the serial communication is asynchronous, additional bits (start and stop) are added to the serial data to indicate the beginning and end. An additional parity bit may be added to the serial character. This bit appears after the last data bit and before the stop bit(s) in the character structure to perform simple error checking on the received data, as shown in Figure.

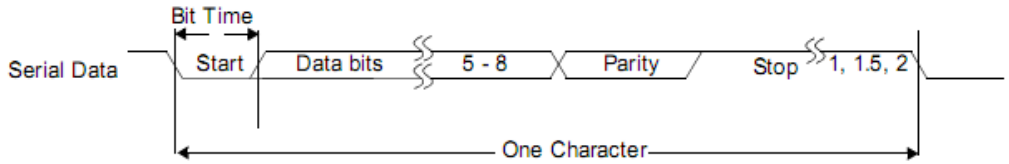

Fig. 19-2 UART Serial protocol

**Baud Clock**
The baud rate is controlled by the serial clock (sclk or pclk in a single clock implementation) and the Divisor Latch Register (DLH and DLL). As the exact number of baud clocks that each bit was transmitted for is known, calculating the mid-point for sampling is not difficult, that is every 16 baud clocks after the mid-point sample of the start bit.

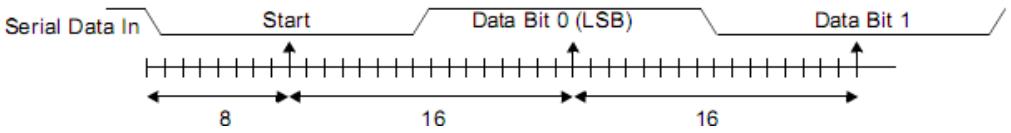

Fig. 19-3 UART baud rate

**FIFO Support**
**1. NONE FIFO MODE**
If FIFO support is not selected, then no FIFOs are implemented and only a single receive data byte and transmit data byte can be stored at a time in the RBR and THR.

**2. FIFO MODE**
The FIFO depth of is 64bytes. The FIFO mode of all the UART is enabled by register FCR[0].

**Interrupts**

Rockchip Confidential

The following interrupt types can be enabled with the IER register.

- Receiver Error
- Receiver Data Available
- Character Timeout (in FIFO mode only)
- Transmitter Holding Register Empty at/below threshold (in Programmable THRE Interrupt mode)
- Modem Status

**DMA Support**

The UART supports DMA signaling with the use of two output signals (dma_tx_req_n and dma_rx_req_n) to indicate when data is ready to be read or when the transmit FIFO is empty.

The dma_tx_req_n signal is asserted under the following conditions:

- When the Transmitter Holding Register is empty in non-FIFO mode.
- When the transmitter FIFO is empty in FIFO mode with Programmable THRE interrupt mode disabled.
- When the transmitter FIFO is at, or below the programmed threshold with Programmable THRE interrupt mode enabled.

The dma_rx_req_n signal is asserted under the following conditions:

- When there is a single character available in the Receive Buffer Register in non-FIFO mode.
- When the Receiver FIFO is at or above the programmed trigger level in FIFO mode.

**Auto Flow Control**

The UART can be configured to have a 16750-compatible Auto RTS and Auto CTS serial data flow control mode available. If FIFOs are not implemented, then this mode cannot be selected. When Auto Flow Control mode has been selected, it can be enabled with the Modem Control Register (MCR[5]). Following figure shows a block diagram of the Auto Flow Control functionality.

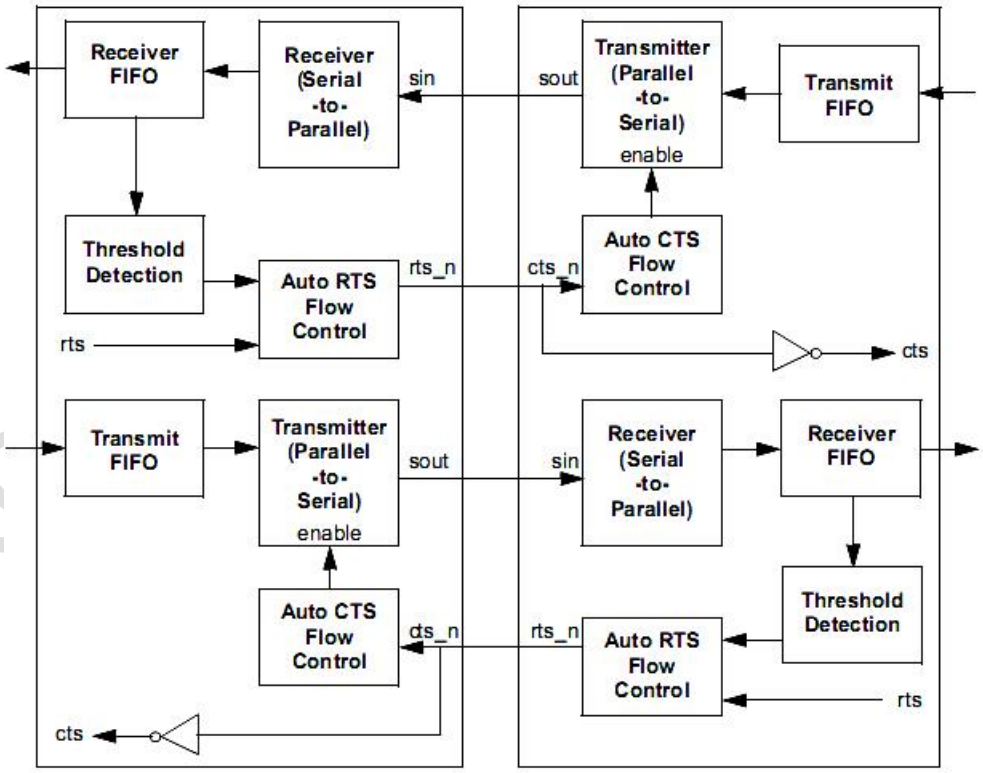

Fig. 19-4 UART Auto flow control block diagram

Auto RTS – Becomes active when the following occurs:

- Auto Flow Control is selected during configuration

Rockchip Confidential

- FIFOs are implemented
- RTS (MCR[1] bit and MCR[5]bit are both set)
- FIFOs are enabled (FCR[0]) bit is set)
- SIR mode is disabled (MCR[6] bit is not set)

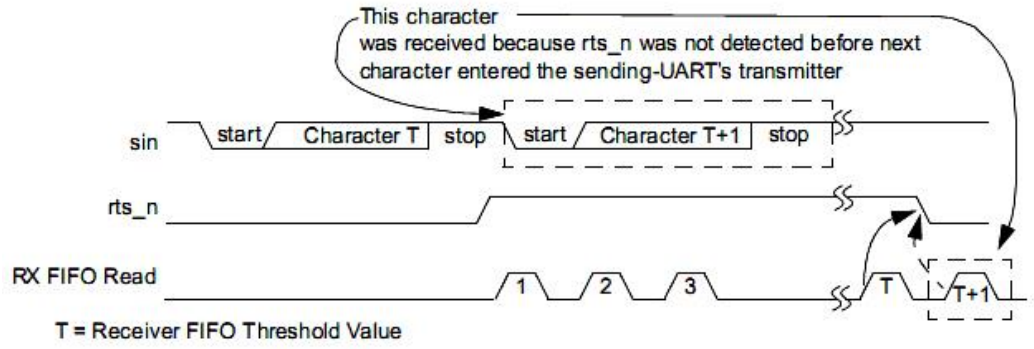

Fig. 19-5 UART AUTO RTS TIMING

Auto CTS – becomes active when the following occurs:

- Auto Flow Control is selected during configuration
- FIFOs are implemented
- AFCE (MCR[5] bit is set)
- FIFOs are enabled through FIFO Control Register FCR[0] bit
- SIR mode is disabled (MCR[6] bit is not set)

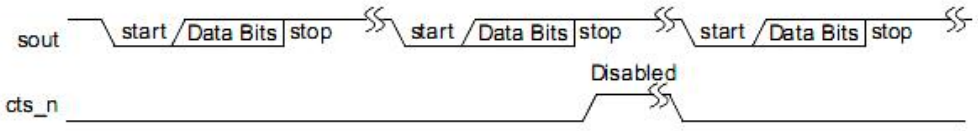

Fig. 19-6 UART AUTO CTS TIMING

# 19.4 Register Description

## 19.4.1 Registers Summary

| Name | Offset | Size | Reset Value | Description |
|---|---|---|---|---|
| UART_RBR | 0x0000 | W | 0x00000000 | Receive Buffer Register |
| UART_DLL | 0x0000 | W | 0x00000000 | Divisor Latch Low |
| UART_THR | 0x0000 | W | 0x00000000 | Transmit Buffer Register |
| UART_DLH | 0x0004 | W | 0x00000000 | Divisor Latch High |

## 19.4.2 Detail Registers Description

**UART_RBR**

Address: Operational Base + offset (0x0000)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:8 | RO | 0x000000 | reserved |
| 7:0 | RO | 0x00 | data_input<br>Data byte received on the serial input port (sin) in UART mode, or the serial infrared input (sir_in) in infrared mode. The data in this register is valid only if the Data Ready (DR) bit in the Line Status Register (LCR) is set. If in non-FIFO mode (FIFO_MODE == NONE) or FIFOs are disabled (FCR[0] set to zero), the data in the RBR must be read before the next data arrives, otherwise it is overwritten, resulting in an over-run error.<br>If in FIFO mode (FIFO_MODE != NONE) and FIFOs are enabled (FCR[0] set to one), this register accesses the head of the receive FIFO. If the receive FIFO is full and this register is not read before the next data character arrives, then the data already in the FIFO is preserved, but any incoming data are lost and an over-run error occurs. |

**UART_DLL**

Address: Operational Base + offset (0x0000)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:8 | RO | 0x000000 | reserved |

Rockchip Confidential

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 7:0 | RW | 0x00 | baud_rate_divisor_l<br>Lower 8 bits of a 16-bit, read/write, Divisor Latch register that contains the baud rate divisor for the UART. This register may only be accessed when the DLAB bit (LCR[7]) is set and the UART is not busy (USR[0] is zero). The output baud rate is equal to the serial clock (pclk if one clock design, sclk if two clock design (CLOCK_MODE == Enabled)) frequency divided by sixteen times the value of the baud rate divisor, as follows: baud rate = (serial clock freq) / (16 * divisor).<br>Note that with the Divisor Latch Registers (DLL and DLH) set to zero, the baud clock is disabled and no serial communications occur. Also, once the DLL is set, at least 8 clock cycles of the slowest UART clock should be allowed to pass before transmitting or receiving data. |

**UART_THR**

Address: Operational Base + offset (0x0000)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:8 | RO | 0x000000 | reserved |
| 7:0 | WO | 0x00 | data_output<br>Data to be transmitted on the serial output port (sout) in UART mode or the serial infrared output (sir_out_n) in infrared mode. Data should only be written to the THR when the THR Empty (THRE) bit (LSR[5]) is set. If in non-FIFO mode or FIFOs are disabled (FCR[0] = 0) and THRE is set, writing a single character to the THR clears the THRE. Any additional writes to the THR before the THRE is set again causes the THR data to be overwritten.<br>If in FIFO mode and FIFOs are enabled (FCR[0] = 1) and THRE is set, 64 characters of data may be written to the THR before the FIFO is full. Any attempt to write data when the FIFO is full results in the write data being lost. |

**UART_DLH**

Address: Operational Base + offset (0x0004)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:8 | RO | 0x000000 | reserved |
| 7:0 | RW | 0x00 | baud_rate_divisor_h<br>Upper 8-bits of a 16-bit, read/write, Divisor Latch register that contains the baud rate divisor for the UART. This register may only be accessed when the DLAB bit (LCR[7]) is set and the UART is not busy (USR[0] is zero). The output baud rate is equal to the serial clock (pclk if one clock design, sclk if two clock design CLOCK_MODE == Enabled)) frequency divided by sixteen times the value of the baud rate divisor, as follows: baud rate = (serial clock freq) / (16 * divisor).<br>Note that with the Divisor Latch Registers (DLL and DLH) set to zero, the baud clock is disabled and no serial communications occur. Also, once the DLH is set, at least 8 clock cycles of the slowest UART clock should be allowed to pass before transmitting or receiving data. |

**UART_IER**

| 7 | RW | 0x0 | prog_thre_int_en<br>Programmable THRE Interrupt Mode Enable that can be written to only when THRE_MODE_USER == Enabled, always readable. This is used to enable/disable the generation of THRE Interrupt.<br>1'b0: Disabled<br>1'b1: Enabled |
| 6:4 | RO | 0x0 | reserved |
| 3 | RW | 0x0 | modem_status_int_en<br>Enable Modem Status Interrupt. This is used to enable/disable the generation of Modem Status Interrupt. This is the fourth highest priority interrupt.<br>1'b0: Disabled<br>1'b1: Enabled |
| 2 | RW | 0x0 | receive_line_status_int_en<br>Enable Receiver Line Status Interrupt. This is used to enable/disable the generation of Receiver Line Status Interrupt. This is the highest priority<br>interrupt.<br>1'b0: Disabled<br>1'b1: Enabled |
| 1 | RW | 0x0 | trans_hold_empty_int_en<br>Enable Transmit Holding Register Empty Interrupt. This is used to enable/disable the generation of Transmitter Holding Register Empty Interrupt. This is the third highest priority interrupt.<br>1'b0: Disabled<br>1'b1: Enabled |
| 0 | RW | 0x0 | receive_data_available_int_en<br>Enable Received Data Available Interrupt. This is used to enable/disable the generation of Received Data Available Interrupt and the Character Timeout Interrupt (if in FIFO mode and FIFOs enabled). These are the second highest priority interrupts.<br>1'b0: Disabled<br>1'b1: Enabled |

**UART_FCR**

Address: Operational Base + offset (0x0008)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:8 | RO | 0x000000 | reserved |
| 7:6 | WO | 0x0 | rcvr_trigger<br>At which the Received Data Available Interrupt is generated. In auto flow control mode it is used to determine when the rts_n signal is de-asserted. It also determines when the dma_rx_req_n signal is asserted in certain modes of operation. For details on DMA support, refer to "DMA Support". The following trigger levels are supported:<br>2'b00: 1 character in the FIFO<br>2'b01: FIFO 1/4 full<br>2'b10: FIFO 1/2 full<br>2'b11: FIFO 2 less than full |

Rockchip Confidencial

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 5:4 | WO | 0x0 | tx_empty_trigger<br>TX Empty Trigger. Writes have no effect when THRE_MODE_USER == Disabled. This is used to select the empty threshold level at which the THRE Interrupts are generated when the mode is active. It also determines when the dma_tx_req_n signal is asserted when in certain modes of operation. For details on DMA support, refer to "DMA Support" . The following trigger levels are supported:<br>2'b00: FIFO empty<br>2'b01: 2 characters in the FIFO<br>2'b10: FIFO 1/4 full<br>2'b11: FIFO 1/2 full |
| 3 | WO | 0x0 | dma_mode<br>DMA Mode. This determines the DMA signaling mode used for the dma_tx_req_n and dma_rx_req_n output signals when additional DMA handshaking signals are not selected (DMA_EXTRA == No). For details on DMA support, refer to DMA Support.<br>1'b0: Mode 0<br>1'b1: Mode 1 |
| 2 | WO | 0x0 | xmit_fifo_reset<br>XMIT FIFO Reset. This resets the control portion of the transmit FIFO and treats the FIFO as empty. This also de-asserts the DMA TX request and single signals when additional DMA handshaking signals are selected (DMA_EXTRA == YES). Note that this bit is 'self-clearing'. It is not necessary to clear this bit. |
| 1 | WO | 0x0 | rcvr_fifo_reset<br>RCVR FIFO Reset. This resets the control portion of the receive FIFO and treats the FIFO as empty. This also de-asserts the DMA RX request and single signals when additional DMA handshaking signals are selected (DMA_EXTRA == YES). Note that this bit is 'self-clearing'. It is not necessary to clear this bit. |
| 0 | WO | 0x0 | fifo_en<br>FIFO Enable. This enables/disables the transmit (XMIT) and receive (RCVR) FIFOs. Whenever the value of this bit is changed both the XMIT and RCVR controller portion of FIFOs is reset. |

**UART_IIR**

Address: Operational Base + offset (0x0008)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:8 | RO | 0x000000 | reserved |
| 7:6 | RO | 0x0 | fifos_en<br>FIFOs Enabled. This is used to indicate whether the FIFOs are enabled or disabled.<br>2'b00: Disabled<br>2'b11: Enabled |
| 5:4 | RO | 0x0 | reserved |

Rockchip Confidential

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 3:0 | RO | 0x1 | int_id<br>Interrupt ID. This indicates the highest priority pending interrupt which can be one of the following types:<br>4'b0000: Modem status<br>4'b0001: No interrupt pending<br>4'b0010: THR empty<br>4'b0100: Received data available<br>4'b0110: Receiver line status<br>4'b0111: Busy detect<br>4'b1100: Character timeout<br>The interrupt priorities are split into four levels that are detailed in Table X.<br>Bit 3 indicates an interrupt can only occur when the FIFOs are enabled and used to distinguish a Character Timeout condition interrupt. |

**UART_LCR**

Address: Operational Base + offset (0x000C)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:8 | RO | 0x000000 | reserved |
| 7 | RW | 0x0 | div_lat_access<br>Divisor Latch Access Bit. Writable only when UART is not busy (USR[0] is zero), always readable. This bit is used to enable reading and writing of the Divisor Latch register (DLL and DLH) to set the baud rate of the UART. This bit must be cleared after initial baud rate setup in order to access other registers. |
| 6 | RW | 0x0 | break_ctrl<br>Break Control Bit. This is used to cause a break condition to be transmitted to the receiving device. If set to one the serial output is forced to the spacing (logic 0) state. When not in Loopback Mode, as determined by MCR[4], the sout line is forced low until the Break bit is cleared. If SIR_MODE == Enabled and active (MCR[6] set to one) the sir_out_n line is continuously pulsed. When in Loopback Mode, the break condition is internally looped back to the receiver and the sir_out_n line is forced low. |
| 5 | RW | 0x0 | stick_parity<br>If UART_16550_COMPATIBLE = NO, then writable only when UART is not busy (USR[0] is 0); otherwise always writable and always readable. This bit is used to force parity value. When PEN, EPS and Stick Parity are set to 1, the parity bit is transmitted and checked as logic 0. If PEN and Stick Parity are set to 1 and EPS is a logic 0, then parity bit is transmitted and checked as a logic 1. If this bit is set to 0, Stick Parity is disabled. |
| 4 | RW | 0x0 | even_parity_sel<br>Even Parity Select. Writable only when UART is not busy (USR[0] is zero), always readable. This is used to select between even and odd parity, when parity is enabled (PEN set to one). If set to one, an even number of logic 1s is transmitted or checked. If set to zero, an odd number of logic 1s is transmitted or checked. |

Rockchip Confidential

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 3 | RW | 0x0 | parity_en<br>Parity Enable. Writable only when UART is not busy (USR[0] is zero), always readable. This bit is used to enable and disable parity generation and detection in transmitted and received serial character respectively.<br>1'b0: Parity disabled<br>1'b1: Parity enabled |
| 2 | RW | 0x0 | stop_bits_num<br>Number of stop bits. Writable only when UART is not busy (USR[0] is zero), always readable. This is used to select the number of stop bits per character that the peripheral transmits and receives. If set to zero, one stop bit is transmitted in the serial data. If set to one and the data bits are set to 5 (LCR[1:0] set to zero) one and a half stop bits is transmitted. Otherwise, two stop bits are transmitted. Note that regardless of the number of stop bits selected, the receiver checks only the first stop bit.<br>1'b0: 1 stop bit<br>1'b1: 1.5 stop bits when DLS (LCR[1:0]) is zero, else 2 stop bit. |
| 1:0 | RW | 0x0 | data_length_sel<br>Data Length Select. Writable only when UART is not busy (USR[0] is zero), always readable. This is used to select the number of data bits per character that the peripheral transmits and receives. The number of bit that may be selected areas follows:<br>2'b00: 5 bits<br>2'b01: 6 bits<br>2'b10: 7 bits<br>2'b11: 8 bits |

**UART_MCR**

Address: Operational Base + offset (0x0010)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:7 | RO | 0x0000000 | reserved |
| 6 | RW | 0x0 | reserved |
| 5 | RW | 0x0 | auto_flow_ctrl_en<br>Auto Flow Control Enable. Writable only when AFCE_MODE == Enabled, always readable. When FIFOs are enabled and the Auto Flow Control Enable (AFCE) bit is set, Auto Flow Control features are enabled as described in "Auto Flow Control".<br>1'b0: Auto Flow Control Mode disabled<br>1'b1: Auto Flow Control Mode enabled |
| 4 | RW | 0x0 | loopback<br>LoopBack Bit. This is used to put the UART into a diagnostic mode for test purposes. If operating in UART mode (SIR_MODE != Enabled or not active, MCR[6] set to zero), data on the sout line is held high, while serial data output is looped back to the sin line, internally. In this mode all the interrupts are fully functional. Also, in loopback mode, the modem control inputs (dsr_n, cts_n, ri_n, dcd_n) are disconnected and the modem control outputs (dtr_n, rts_n, out1_n, out2_n) are looped back to the inputs, internally. If operating in infrared mode (SIR_MODE == Enabled AND active, MCR[6] set to one), data on the sir_out_n line is held low, while serial data output is inverted and looped back to the sir_in line. |

Rockchip Confidential

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 3 | RW | 0x0 | out2<br>OUT2. This is used to directly control the user-designated Output2 (out2_n) output. The value written to this location is inverted and driven out on out2_n, that is:<br>1'b0: Out2_n de-asserted (logic 1)<br>1'b1: Out2_n asserted (logic 0)<br>Note that in Loopback mode (MCR[4] set to one), the out2_n output is held inactive high while the value of this location is internally looped back to an input. |
| 2 | RW | 0x0 | out1<br>OUT1. This is used to directly control the user-designated Output1 (out1_n) output. The value written to this location is inverted and driven out on out1_n, that is:<br>1'b0: Out1_n de-asserted (logic 1)<br>1'b1: Out1_n asserted (logic 0)<br>Note that in Loopback mode (MCR[4] set to one), the out1_n output is held inactive high while the value of this location is internally looped back to an input. |
| 1 | RW | 0x0 | req_to_send<br>Request to Send. This is used to directly control the Request to Send (rts_n) output. The Request To Send (rts_n) output is used to inform the modem or data set that the UART is ready to exchange data. When Auto RTS Flow Control is not enabled (MCR[5] set to zero), the rts_n signal is set low by programming MCR[1] (RTS) to a high. In Auto Flow Control, AFCE_MODE == Enabled and active (MCR[5] set to one) and FIFOs enable (FCR[0] set to one), the rts_n output is controlled in the same way, but is also gated with the receiver FIFO threshold trigger (rts_n is inactive high when above the threshold). The rts_n signal is de-asserted when MCR[1] is set low. Note that in Loopback mode (MCR[4] set to one), the rts_n output is held inactive high while the value of this location is internally looped back to an input. |
| 0 | RW | 0x0 | data_terminal_ready<br>Data Terminal Ready. This is used to directly control the Data Terminal Ready (dtr_n) output. The value written to this location is inverted and driven out on dtr_n, that is:<br>1'b0: dtr_n de-asserted (logic 1)<br>1'b1: dtr_n asserted (logic 0)<br>The Data Terminal Ready output is used to inform the modem or data set that the UART is ready to establish communications. Note that in Loopback mode (MCR[4] set to one), the dtr_n output is held inactive |

**UART_LSR**

Address: Operational Base + offset (0x0014)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:8 | RO | 0x000000 | reserved |

Rockchip Confidential

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 7 | RO | 0x0 | receiver_fifo_error<br>Receiver FIFO Error bit. This bit is only relevant when FIFO_MODE != NONE AND FIFOs are enabled (FCR[0] set to one). This is used to indicate if there is at least one parity error, framing error, or break indication in the FIFO.<br>1'b0: No error in RX FIFO<br>1'b1: Error in RX FIFO<br>This bit is cleared when the LSR is read and the character with the error is at the top of the receiver FIFO and there are no subsequent errors in the FIFO. |
| 6 | RO | 0x1 | trans_empty<br>Transmitter Empty bit. If in FIFO mode (FIFO_MODE != NONE) and FIFOs enabled (FCR[0] set to one), this bit is set whenever the Transmitter Shift Register and the FIFO are both empty. If in non-FIFO mode or FIFOs are disabled, this bit is set whenever the Transmitter Holding Register and the Transmitter Shift Register are both empty. |
| 5 | RO | 0x1 | trans_hold_reg_empty<br>Transmit Holding Register Empty bit. If THRE_MODE_USER == Disabled or THRE mode is disabled (IER[7] set to zero) and regardless of FIFO's being implemented/enabled or not, this bit indicates that the THR or TX FIFO is empty.<br>This bit is set whenever data is transferred from the THR or TX FIFO to the transmitter shift register and no new data has been written to the THR or TX FIFO. This also causes a THRE Interrupt to occur, if the THRE Interrupt is enabled. If THRE_MODE_USER == Enabled AND FIFO_MODE != NONE and both modes are active (IER[7] set to one and FCR[0] set to one respectively), the functionality is switched to indicate the transmitter FIFO is full, and no longer controls THRE interrupts, which are then controlled by the FCR[5:4] threshold setting. |
| 4 | RO | 0x0 | break_int<br>Break Interrupt bit. This is used to indicate the detection of a break sequence on the serial input data. If in UART mode (SIR_MODE == Disabled), it is set whenever the serial input, sin, is held in a logic '0' state for longer than the sum of start time + data bits + parity + stop bits. If in infrared mode (SIR_MODE == Enabled), it is set whenever the serial input, sir_in, is continuously pulsed to logic '0' for longer than the sum of start time + data bits + parity + stop bits. A break condition on serial input causes one and only one character, consisting of all zeros, to be received by the UART. In the FIFO mode, the character associated with the break condition is carried through the FIFO and is revealed when the character is at the top of the FIFO. Reading the LSR clears the BI bit. In the non-FIFO mode, the BI indication occurs immediately and persists until the LSR is read. |

Rockchip Confidential

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 3 | RO | 0x0 | framing_error<br>Framing Error bit. This is used to indicate the occurrence of a framing error in the receiver. A framing error occurs when the receiver does not detect a valid STOP bit in the received data. In the FIFO mode, since the framing error is associated with a character received, it is revealed when the character with the framing error is at the top of the FIFO. When a framing error occurs, the UART tries to re-synchronize. It does this by assuming that the error was due to the start bit of the next character and then continues receiving the other bit i.e. data, and/or parity and stop. It should be noted that the Framing Error (FE) bit (LSR[3]) is set if a break interrupt has occurred, as indicated by Break Interrupt (BI) bit (LSR[4]).<br>1'b0: No framing error<br>1'b1: Framing error<br>Reading the LSR clears the FE bit. |
| 2 | RO | 0x0 | parity_error<br>Parity Error bit. This is used to indicate the occurrence of a parity error in the receiver if the Parity Enable (PEN) bit (LCR[3]) is set. In the FIFO mode, since the parity error is associated with a character received, it is revealed when the character with the parity error arrives at the top of the FIFO. It should be noted that the Parity Error (PE) bit (LSR[2]) is set if a break interrupt has occurred, as indicated by Break Interrupt (BI) bit (LSR[4]).<br>1'b0: No parity error<br>1'b1: Parity error<br>Reading the LSR clears the PE bit. |
| 1 | RO | 0x0 | overrun_error<br>Overrun error bit. This is used to indicate the occurrence of an overrun error. This occurs if a new data character was received before the previous data was read. In the non-FIFO mode, the OE bit is set when a new character arrives in the receiver before the previous character was read from the RBR. When this happens, the data in the RBR is overwritten. In the FIFO mode, an overrun error occurs when the FIFO is full and a new character arrives at the receiver. The data in the FIFO is retained and the data in the receive shift register is lost.<br>1'b0: No overrun error<br>1'b1: Overrun error<br>Reading the LSR clears the OE bit. |
| 0 | RO | 0x0 | data_ready<br>Data Ready bit. This is used to indicate that the receiver contains at least one character in the RBR or the receiver FIFO.<br>1'b0: No data ready<br>1'b1: Data ready<br>This bit is cleared when the RBR is read in non-FIFO mode, or when the receiver FIFO is empty, in FIFO mode. |

**UART_SRBR**

Address: Operational Base + offset (0x0030)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:8 | RO | 0x000000 | reserved |

Rockchip Confidential

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 7:0 | RO | 0x00 | shadow_rbr<br>This is a shadow register for the RBR and has been allocated sixteen 32-bit locations (0x30-0x6c) so as to accommodate burst accesses from the master. This register contains the data byte received on the serial input port (sin) in UART mode or the serial infrared input (sir_in) in infrared mode. The data in this register is valid only if the Data Ready (DR) bit in the Line status Register (LSR) is set. If in non-FIFO mode (FIFO_MODE == NONE) or FIFOs are disabled (FCR[0] set to zero), the data in the RBR must be read before the next data arrives, otherwise it is overwritten, resulting in an overrun error. If in FIFO mode (FIFO_MODE != NONE) and FIFOs are enabled (FCR[0] set to one), this register accesses the head of the receive FIFO. If the receive FIFO is full and this register is not read before the next data character arrives, then the data already in the FIFO are preserved, but any incoming data is lost. An overrun error also occurs. |

**UART_STHR**

Address: Operational Base + offset (0x0030)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:8 | RO | 0x000000 | reserved |
| 7:0 | WO | 0x00 | shadow_thr<br>This is a shadow register for the THR and has been allocated sixteen 32-bit locations(0x30-0x6c) so as to accommodate burst accesses from the master. This register contains data to be transmitted on the serial output port (sout) in UART mode or the serial infrared output (sir_out_n) in infrared mode. Data should only be written to the THR when the THR Empty (THRE) bit (LSR[5]) is set. If in non-FIFO mode or FIFOs are disabled (FCR[0] set to zero) and THRE is set, writing a single character to the THR clears the THRE. Any additional writes to the THR before the THRE is set again causes the THR data to be overwritten. If in FIFO mode and FIFOs are enabled (FCR[0] set to one) and THRE is set, x number of characters of data may be written to the THR before the FIFO is full. The number x (default=16) is determined by the value of FIFO Depth that you set during configuration. Any attempt to write data when the FIFO is full results in the write data being lost. |

## 19.6 Application Notes

### 19.6.1 None FIFO Mode Transfer Flow

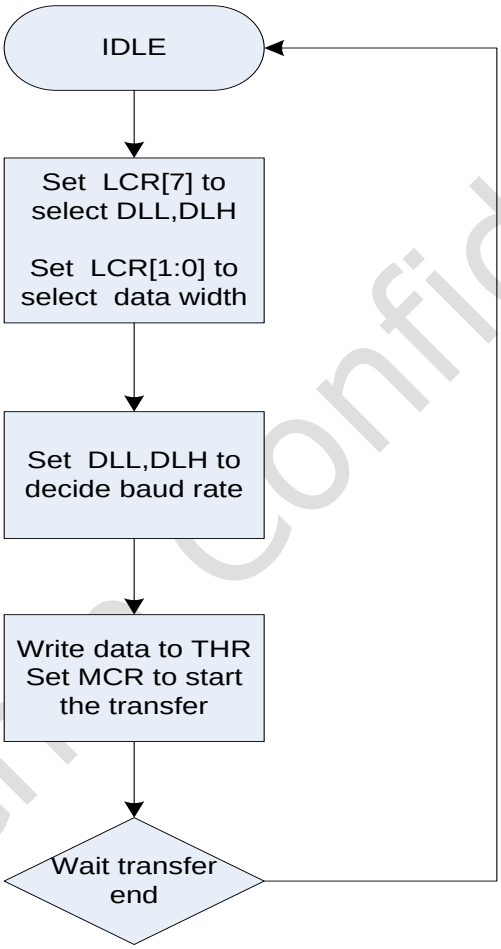

Fig. 19-7 UART none fifo mode

### 19.6.2 FIFO Mode Transfer Flow

Rockchip Confidencial

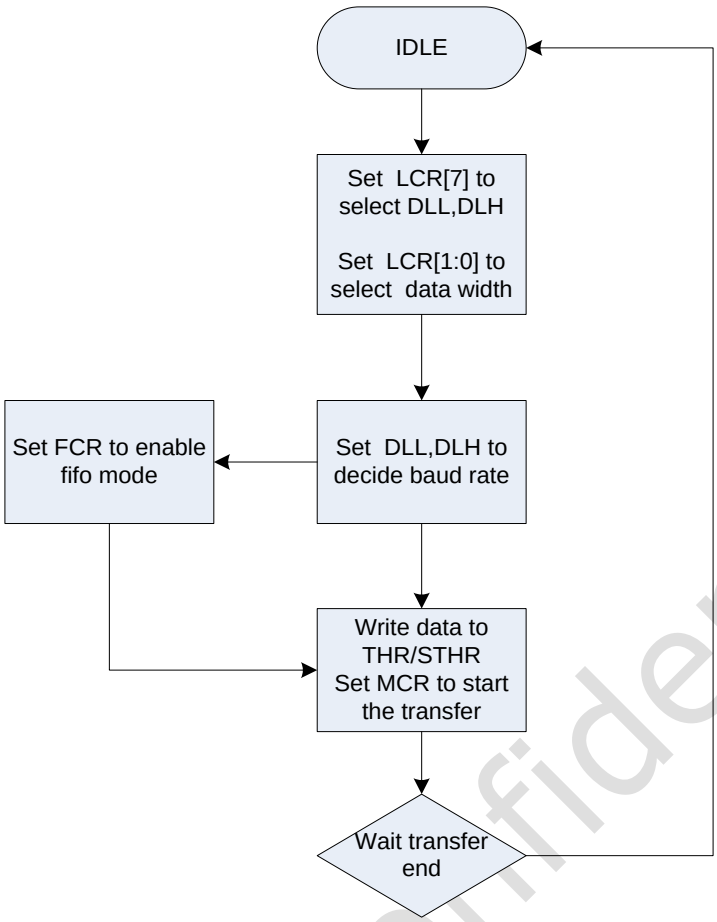

Fig. 19-8 UART fifo mode

The UART is an APB slave performing:
Serial-to-parallel conversion on data received from a peripheral device. Parallel-to-serial conversion on data transmitted to the peripheral device. The CPU reads and writes data and control/status information through the APB interface. The transmitting and receiving paths are buffered with internal FIFO memories enabling up to 64-bytes to be stored independently in both transmit and receive modes. A baud rate generator can generate a common transmit and receive internal clock input. The baud rates will depend on the internal clock frequency. The UART will also provide transmit, receive and exception interrupts to system. A DMA interface is implemented for improving the system performance.

## 19.6.3 Baud Rate Calculation

### UART clock generation

The following figures shows the UART clock generation. UARTs source clocks can be selected from different PLL outputs. UART clocks can be generated by 1 to 64 division of its source clock, or can be fractionally divided again, or be provided by XIN24M.

Rockchip Confidencial

## UART baud rate configuration

The following table provides some reference configuration for different UART baud rates.

Table 19-11 UART baud rate configuration

| Baud Rate | Reference Configuration |
|---|---|
| 115.2 Kbps | Configure PLL to get 648MHz clock output; Divide 648MHz clock by 1152/50625 to get 14.7456MHz clock; Configure UART_DLL to 8. |
| 460.8 Kbps | Configure PLL to get 648MHz clock output; Divide 648MHz clock by 1152/50625 to get 14.7456MHz clock; Configure UART_DLL to 2. |
| 921.6 Kbps | Configure PLL to get 648MHz clock output; Divide 648MHz clock by 1152/50625 to get 14.7456MHz clock; Configure UART_DLL to 1. |
| 1.5 Mbps | Choose PLL to get 384MHz clock output; Divide 384MHz clock by 16 to get 24MHz clock; Configure UART_DLL to 1. |
| 3 Mbps | Choose PLL to get 384MHz clock output; Divide 384MHz clock by 8 to get 48MHz clock; Configure UART_DLL to 1. |
| 4 Mbps | Configure PLL to get 384MHz clock output; Divide 384MHz clock by 6 to get 64MHz clock; Configure UART_DLL to 1. |

# Chapter 20 GPIO

## 20.1 Overview

GPIO is a programmable General Purpose Programming I/O peripheral. This component is an APB slave device. GPIO controls the output data and direction of external I/O pads. It can also read back the data on external pads using memory-mapped registers.
GPIO supports the following features:

- 32 bits APB data bus width
- Up to 32 independently configurable signals
- Software control registers with write mask for each bit of each signal
- Configurable debounce logic with a slow clock to debounce interrupts
- Configurable interrupt mode
- Two virtual OS with independent control registers can be supported
- In two virtual OS model, each OS has independent interrupt
- Not in two virtual OS model, two interrupts with priority can be set

## 20.2 Block Diagram

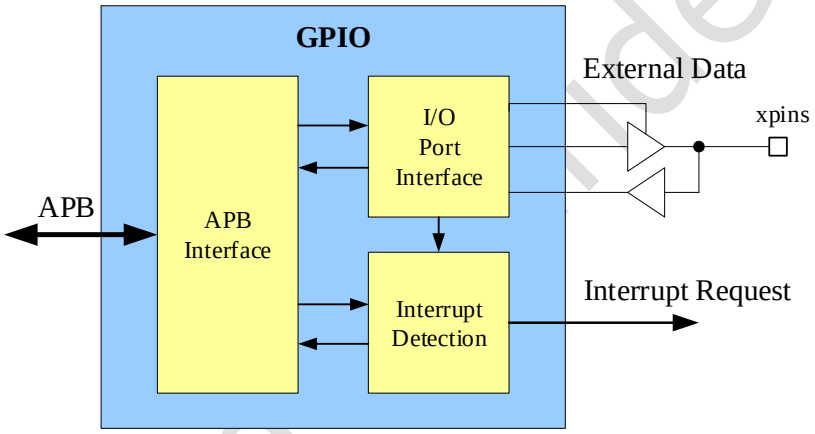

Fig. 20-1 GPIO Block Diagram

GPIO is comprised of:

- APB Interface

The APB Interface implements the APB slave operation. Its data bus width is 32 bits.

- I/O Port Interface

External data interface to or from I/O pads.

- Interrupt Detection
  Interrupt interface to or from interrupt controller.

## 20.3 Function Description

### 20.3.1 Data Control

Under software control, the data and direction control for the signal are sourced from the port data registers (GPIO_SWPORT_DR_L/GPIO_SWPORT_DR_H) and direction control registers (GPIO_SWPORT_DDR_L/GPIO_SWPORT_DRR_H).
The direction of the external I/O pad is controlled by the value of the port data direction registers. The data written to these memory-mapped registers gets mapped onto an output signal (gpio_port_ddr) of the GPIO peripheral. This output signal controls the direction of an external I/O pad. The default data direction is Input.
The data written to the port data registers drives the output buffer (gpio_port_dr) of the I/O pad.
External data are input on the external data signal (gpio_ext_port). Reading the external signal register (GPIO_EXT_PORT) shows the value of this signal, regardless of the direction. This register is read-only, meaning that it cannot be written from the APB software interface.

Rockchip Confidential

### 20.3.2 Interrupts

I/O port can be programmed to accept external signals as interrupt sources on any of the bits of the signal. The type of interrupt is programmable with one of the following settings:

- Active-high and level
- Active-low and level
- Rising edge
- Falling edge
- Both the rising edge and the falling edge

The interrupts can be masked by programming the GPIO_INT_MASK_L/GPIO_INT_MASK_H registers. The interrupt status can be read before masking (GPIO_INT_RAWSTATUS) and after masking (GPIO_INT_STATUS).

For edge-sensitive interrupts, the Interrupt Service Routine (ISR) can clear the interrupt by writing a 1 to the corresponding bit of the GPIO_PORT_EOI_L/GPIO_PORT_EOI_H registers. This write operation also clears the interrupt status and raw status registers. Writing to the interrupt clear registers has no effect on level-sensitive interrupts. If level-sensitive interrupts cause the processor to interrupt, then the ISR can poll the interrupt raw status register until the interrupt source disappears, or it can write to the interrupt mask register to mask the interrupt before exiting the ISR. If the ISR exits without masking or disabling the interrupt prior to exiting, then the level-sensitive interrupt repeatedly requests an interrupt until the interrupt is cleared at the source.

The interrupts are combined into an active-high interrupt output signal. In order to mask the combined interrupt, all individual interrupts have to be masked. The single combined interrupt does not have its own mask bit.

Whenever I/O port is configured for interrupts, the data direction must be set to Input. If the data direction is reprogrammed to Output, then any pending edge-sensitive interrupts are not lost. However, no new interrupts are generated, and level-sensitive interrupts are lost.

Interrupt signals are internally synchronized to a system clock pclk_intr, which is connected to the APB bus clock pclk. Therefore, the pclk needs to be running for interrupt detection.

### 20.3.3 Debounce Operation

The external signal can be debounced to remove any spurious glitches that are less than one period of the external debouncing clock.

When an input interrupt signal is debounced using a slow debounce clock (external input clock dbclk or internal divided clock dbclk_div), the signal must be active for a minimum of two cycles of the debounce clock to guarantee that it is registered. Any input pulse widths less than a debounce clock period are bounced. A pulse width between one and two debounce clock widths may or may not propagate, depending on its phase relationship to the debounce clock. If the input pulse spans two rising edges of the debounce clock, it is registered. If it spans only one rising edge, it is not registered.

The debounce function can be controlled by programming the debounce enable registers (GPIO_DEBOUNCE_L/GPIO_DEBOUNCE_H), debounce clock divide enable registers (GPIO_DBCLK_DIV_EN_L/GPIO_DBCLK_DIV_EN_H) and debounce clock divide control register (GPIO_DBCLK_DIV_CON).

### 20.3.4 Two OS Operation and Tow Interrupts

To select this model, virtual enable register should be set(GPIO_VIRTUAL_EN). Then all the configure can be allotted to two OS（for example OS_A and OS_B). OS_A will use the original address offset, OS_B will use the offset + 0x1000. The 32 bit I/O port should also be allotted to the OS by setting reg group registers(GPIO_REG_GROUP_L and GPIO_REG_GROUP_H). Once reg group is set, the I/O operation can only be used by the setting address offset. Each OS has its own interrupt for I/O port, this is depended on reg group.

If virtual enable register is disable, reg group can also be used to allotted I/O interrupt. These two independent interrupts may be used for priority interrupt setting.

## 20.4 Register Description

This section describes the control/status registers of the design. Software should read and

Rockchip Confidential

write these registers using 32-bits accesses. There are five GPIOs (GPIO0 in PD_PMU, GPIO1/GPIO2/GPIO3/GPIO4 in PD_BUS), and each of them has same register group. Therefore, five GPIOs' register groups have five different base addresses.

### 20.4.1 Registers Summary

| Name | Offset | Size | Reset Value | Description |
|---|---|---|---|---|
| GPIO_SWPORT_DR_L | 0x0000 | W | 0x00000000 | Port Data Register (Low) |
| GPIO_SWPORT_DR_H | 0x0004 | W | 0x00000000 | Port Data Register (High) |
| GPIO_SWPORT_DDR_L | 0x0008 | W | 0x00000000 | Port Data Direction Register (Low) |
| GPIO_SWPORT_DDR_H | 0x000C | W | 0x00000000 | Port Data Direction Register (High) |
| GPIO_INT_EN_L | 0x0010 | W | 0x00000000 | Interrupt Enable Register (Low) |
| GPIO_INT_EN_H | 0x0014 | W | 0x00000000 | Interrupt Enable Register (High) |
| GPIO_INT_MASK_L | 0x0018 | W | 0x00000000 | Interrupt Mask Register (Low) |
| GPIO_INT_MASK_H | 0x001C | W | 0x00000000 | Interrupt Mask Register (High) |
| GPIO_INT_TYPE_L | 0x0020 | W | 0x00000000 | Interrupt Level Register (Low) |
| GPIO_INT_TYPE_H | 0x0024 | W | 0x00000000 | Interrupt Level Register (High) |
| GPIO_INT_POLARITY_L | 0x0028 | W | 0x00000000 | Interrupt Polarity Register (Low) |
| GPIO_INT_POLARITY_H | 0x002C | W | 0x00000000 | Interrupt Polarity Register (High) |
| GPIO_INT_BOTHEDGE_L | 0x0030 | W | 0x00000000 | Interrupt Both Edge Type Register (Low) |
| GPIO_INT_BOTHEDGE_H | 0x0034 | W | 0x00000000 | Interrupt Both Edge Type Register (High) |
| GPIO_DEBOUNCE_L | 0x0038 | W | 0x00000000 | Debounce Enable Register (Low) |
| GPIO_DEBOUNCE_H | 0x003C | W | 0x00000000 | Debounce Enable Register (High) |
| GPIO_DBCLK_DIV_EN_L | 0x0040 | W | 0x00000000 | DBCLK Divide Enable Register (Low) |
| GPIO_DBCLK_DIV_EN_H | 0x0044 | W | 0x00000000 | DBCLK Divide Enable Register (High) |
| GPIO_DBCLK_DIV_CON | 0x0048 | W | 0x00000001 | DBCLK Divide Control Register |
| GPIO_INT_STATUS | 0x0050 | W | 0x00000000 | Interrupt Status Register |
| GPIO_INT_RAWSTATUS | 0x0058 | W | 0x00000000 | Interrupt Raw Status Register |
| GPIO_PORT_EOI_L | 0x0060 | W | 0x00000000 | Interrupt Clear Register (Low) |
| GPIO_PORT_EOI_H | 0x0064 | W | 0x00000000 | Interrupt Clear Register (High) |
| GPIO_EXT_PORT | 0x0070 | W | 0x00000000 | External Port Data Register |
| GPIO_VER_ID | 0x0078 | W | 0x0101157C | Version ID Register |
| GPIO_GPIO_REG_GROUP_L | 0x0100 | W | 0x00000000 | GPIO Group Control |
| GPIO_GPIO_REG_GROUP_H | 0x0104 | W | 0x0000FFFF | GPIO Group Control |
| GPIO_GPIO_VIRTUAL_EN | 0x0108 | W | 0x00000000 | GPIO Virtual Enable |

*Notes: Unused Module Pin is tied to zero!*

Rockchip Confidential

## 20.6 Application Notes

- Reading from an unused location or unused bits in a particular register always returns zeros. There is no error mechanism in the APB.
- Programming the GPIO registers for interrupt detection should be completed prior to enabling the interrupts in order to prevent spurious glitches on the interrupt output signal to the interrupt controller.

# Chapter 21 I2C Interface

## 21.1 Overview

The Inter-Integrated Circuit (I2C) is a two wired (SCL and SDA), bi-directional serial bus that provides an efficient and simple method of information exchange between devices. This I2C bus controller supports master mode acting as a bridge between AMBA protocol and generic I2C bus system.

I2C Controller supports the following features:

- Support 9 independent I2C: I2C0~8, with 42 pairs IOs.
- Item Compatible with I2C-bus
- AMBA APB slave interface
- Supports master mode of I2C bus
- Software programmable clock frequency and transfer rate up to 400Kbit/sec
- Supports 7 bits and 10 bits addressing modes
- Interrupt or polling driven multiple bytes data transfer
- Clock stretching and wait state generation
- Filter out glitch on SCL and SDA

## 21.2 Block Diagram

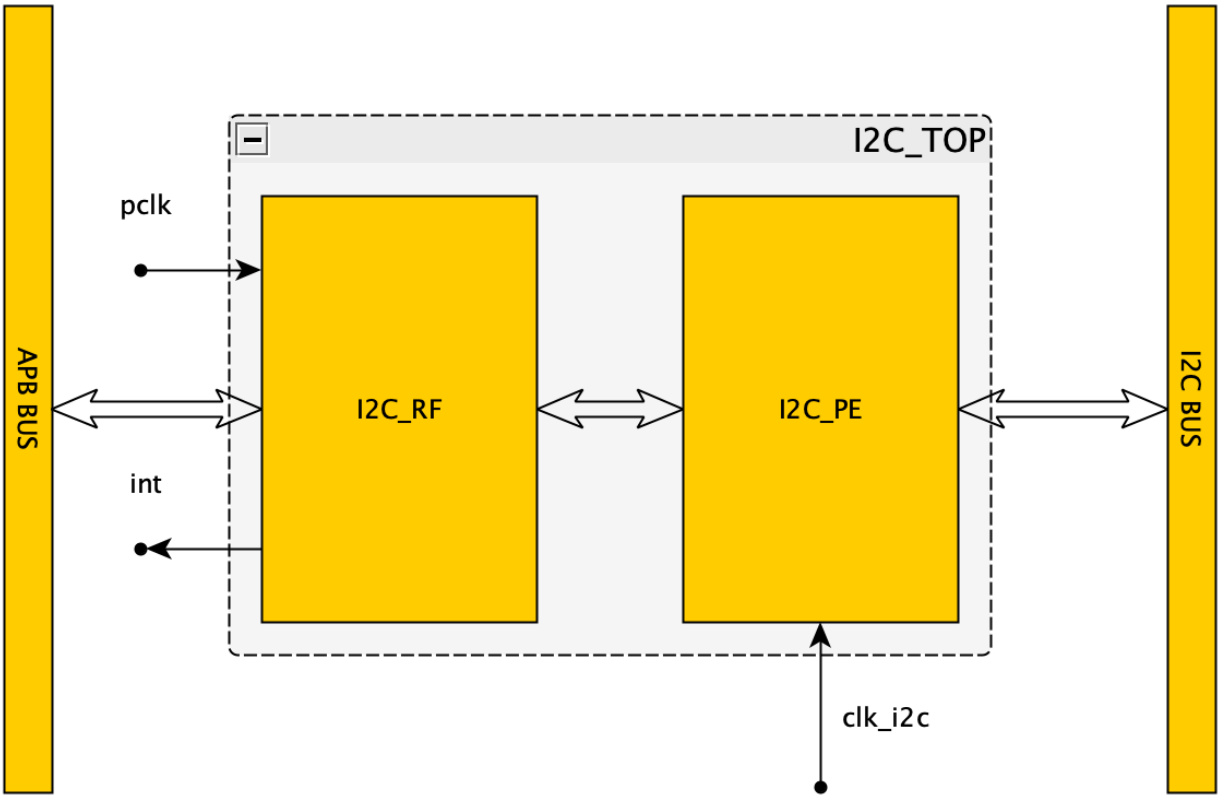

Fig. 21-1 I2C architecture

### 21.2.1 I2C_RF

I2C_RF module is used to control the I2C controller operation by the host with APB interface. It implements the register set and the interrupt functionality. The I2C_RF component operates synchronously with the pclk.

### 21.2.2 I2C_PE

I2C_PE module implements the I2C master operation for transmit data to and receive data from other I2C devices. The I2C master controller operates synchronously with the clk_i2c.

### 21.2.3 I2C_TOP

I2C_TOP module is the top module of the I2C controller.

## 21.3 Function Description

This chapter provides a description about the functions and behavior under various conditions.
The I2C controller supports only Master function. It supports the 7-bits/10-bits addressing mode and support general call address. The maximum clock frequency and transfer rate can be up to 400Kbit/sec.
The operations of I2C controller is divided to 2 parts and described separately: initialization and master mode programming.

### 21.3.1 Initialization

The I2C controller is based on AMBA APB bus architecture and usually is part of a SOC. So before I2C operates, some system setting and configuration must be conformed, which includes:

- I2C interrupt connection type: CPU interrupt scheme should be considered. If the I2C interrupt is connected to extra Interrupt Controller module, we need decide the INTC vector.
- I2C Clock Rate: The I2C controller uses the APB clock to configure controller and uses clk_i2c as the working clock. The correct register setting is subject to the system requirement.

### 21.3.2 Master Mode Programming

- SCL Clock
  When the I2C controller is programmed in Master mode, the SCL frequency is determined by I2C_CLKDIV register. The SCL frequency is calculated by the following formula:
  SCL Divisor = 8*(CLKDIVL + 1 + CLKDIVH + 1); clk_i2c = 100MHz~200MHz.
  SCL = clk_i2c/ SCLK Divisor.

- Data Receiver Register Access
  When the I2C controller received MRXCNT bytes data, CPU can get the data through register RXDATA0 ~ RXDATA7. The controller can receive up to 32 bytes' data in one transaction.
  When MRXCNT register is written, the I2C controller will start to drive SCL to receive data.

- Transmit Transmitter Register
  Data to transmit are written to TXDATA0~7 by CPU. The controller can transmit up to 32 bytes' data in one transaction. The lower byte will be transmitted first.
  When MTXCNT register is written, the I2C controller will start to transmit data.

- Start Command
  Write 1 to I2C_CON[3], the controller will send I2C start command.

- Stop Command
  Write 1 to I2C_CON[4], the controller will send I2C stop command.

- I2C Operation mode
  There are four i2c operation modes.
  - When I2C_CON[2:1] is 2'b00, the controller transmit all valid data in TXDATA0~TXDATA7 byte by byte. The controller will transmit lower byte first.
  - When I2C_CON[2:1] is 2'b01, the controller will transmit device address in MRXADDR first (Write/Read bit = 0) and then transmit device register address in MRXRADDR. After that, the controller will assert restart signal and resend MRXADDR

Rockchip Confidential

(Write/Read bit = 1). At last, the controller enter receive mode.
- When I2C_CON[2:1] is 2'b10, the controller is in receive mode, it will trigger clock to read MRXCNT byte data.
- When I2C_CON[2:1] is 2'b11, the controller will transmit device address in MRXADDR first (Write/Read bit = 1) and then transmit device register address in MRXRADDR. After that, the controller will assert restart signal and resend MRXADDR (Write/Read bit = 1). At last, the controller enter receive mode.

- Read/Write Command
  - When I2C_OPMODE(I2C_CON[2:1]) is 2'b01 or 2'b11, the Read/Write command bit is decided by controller itself.
  - In RX only mode (I2C_CON[2:1] is 2'b10), the Read/Write command bit is decided by MRXADDR[0].
  - In TX only mode (I2C_CON[[2:1] is 2'b00), the Read/Write command bit is decided by TXDATA[0].

- Master Interrupt Condition
  There are 7 interrupt bits in I2C_ISR register related to master mode.
  - Byte transmitted finish interrupt (Bit 0): The bit is asserted when Master completed transmitting a byte.
  - Byte received finish interrupt (Bit 1): The bit is asserted when Master completed receiving a byte.
  - MTXCNT bytes data transmitted finish interrupt (Bit 2): The bit is asserted when Master completed transmitting MTXCNT bytes.
  - MRXCNT bytes data received finish interrupt (Bit 3): The bit is asserted when Master completed receiving MRXCNT bytes.
  - Start interrupt (Bit 4): The bit is asserted when Master finished asserting start command to I2C bus.
  - Stop interrupt (Bit 5): The bit is asserted when Master finished asserting stop command to I2C bus.
  - NAK received interrupt (Bit 6): The bit is asserted when Master received a NAK handshake.

- Last byte acknowledge control
  - If I2C_CON[5] is 1, the I2C controller will transmit NAK handshake to slave when the last byte received in RX only mode.
  - If I2C_CON[5] is 0, the I2C controller will transmit ACK handshake to slave when the last byte received in RX only mode.

- How to handle NAK handshake received
  - If I2C_CON[6] is 1, the I2C controller will stop all transactions when NAK handshake received. And the software should take responsibility to handle the problem.
  - If I2C_CON[6] is 0, the I2C controller will ignore all NAK handshake received.

- I2C controller data transfer waveform
  - Bit transferring
    - Data Validity
      The SDA line must be stable during the high period of SCL, and the data on SDA line can only be changed when SCL is in low state.

Rockchip Confidential

Copyright 2022 © Rockchip Electronics Co., Ltd. 

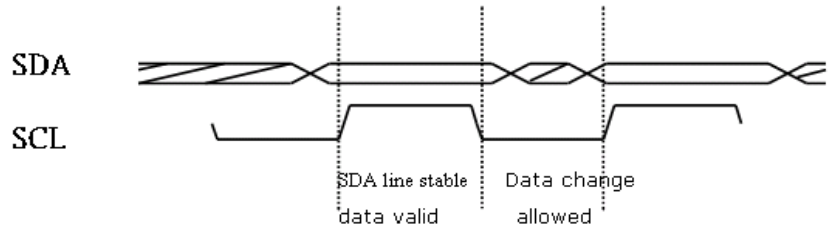

Fig. 21-2 I2C DATA Validity

- START and STOP conditions
  START condition occurs when SDA goes low while SCL is in high period. STOP condition is generated when SDA line goes high while SCL is in high state.

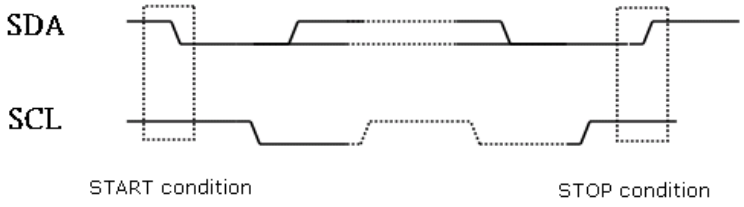

Fig. 21-3 I2C Start and stop conditions

- Data transfer
  - Acknowledge
    After a byte of data transferring (clocks labeled as 1~8), in 9th clock the receiver must assert an ACK signal on SDA line, if the receiver pulls SDA line to low, it means "ACK", on the contrary, it's "NOT ACK".

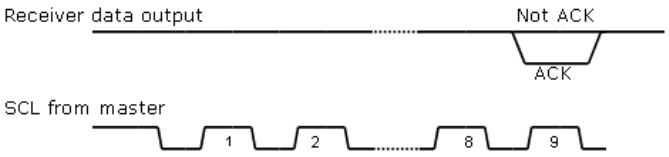

Fig. 21-4 I2C Acknowledge

  - Byte transfer
    The master own I2C bus might initiate multi byte to transfer to a slave. The transfer starts from a "START" command and ends in a "STOP" command. After every byte transfer, the receiver must reply an ACK to transmitter.

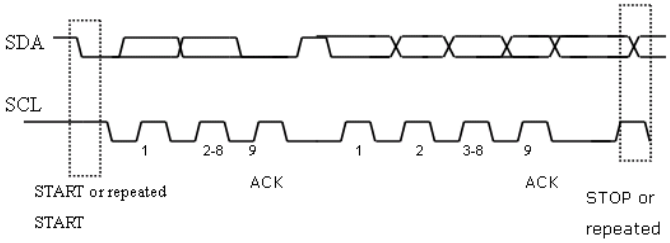

Fig. 21-5 I2C byte transfer

# 21.4 Register Description

## 21.4.1 Registers Summary

| Name | Offset | Size | Reset Value | Description |
|---|---|---|---|---|
| RKI2C_CON | 0x0000 | W | 0x00050000 | Control register |

Rockchip Confidential

| Name | Offset | Size | Reset Value | Description |
|---|---|---|---|---|
| RKI2C_CLKDIV | 0x0004 | W | 0x00000001 | Clock divider register I2C CLK = PCLK / (16*CLKDIV) |
| RKI2C_MRXADDR | 0x0008 | W | 0x00000000 | The slave address accessed for master rx mode |
| RKI2C_MRXRADDR | 0x000C | W | 0x00000000 | The slave register address accessed for master rx mode |
| RKI2C_MTXCNT | 0x0010 | W | 0x00000000 | Master transmit count, specify the total bytes to be transmit (0~32) |
| RKI2C_MRXCNT | 0x0014 | W | 0x00000000 | Master rx count, specify the total bytes to be recieved(0~32) |

## 21.7 Application Notes

The I2C controller core operation flow chart below is to describe how the software configures and performs an I2C transaction through this I2C controller core. Descriptions are divided into 3 sections, transmit only mode, receive only mode, and mix mode. Users are strongly advised to follow:

- Transmit only mode (I2C_CON[1:0]=2'b00)

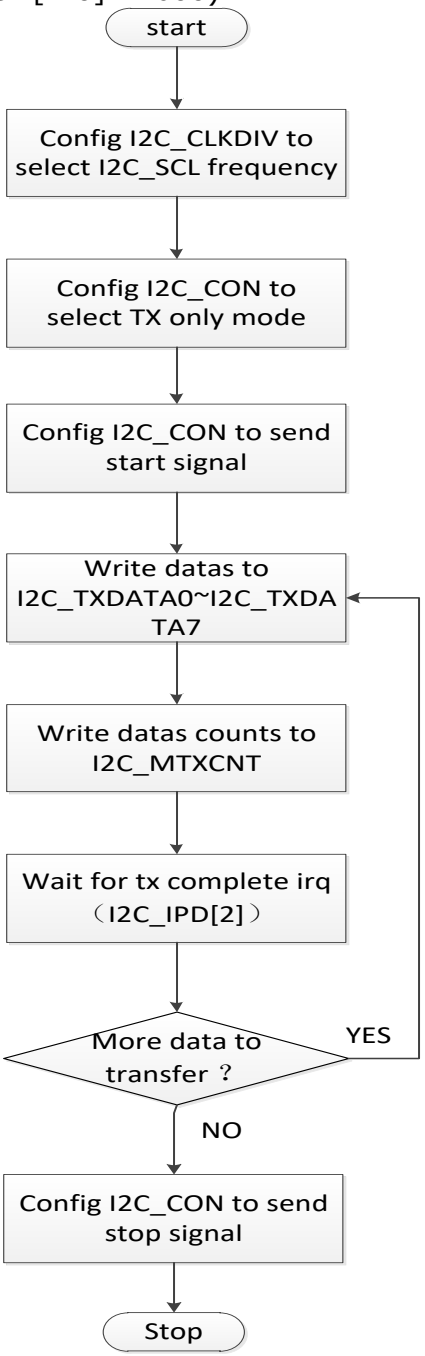

Fig. 21-6 I2C Flow chat for transmit only mode

Copyright 2022 © Rockchip Electronics Co., Ltd.

- Receive only mode (I2C_CON[1:0]=2'b10)

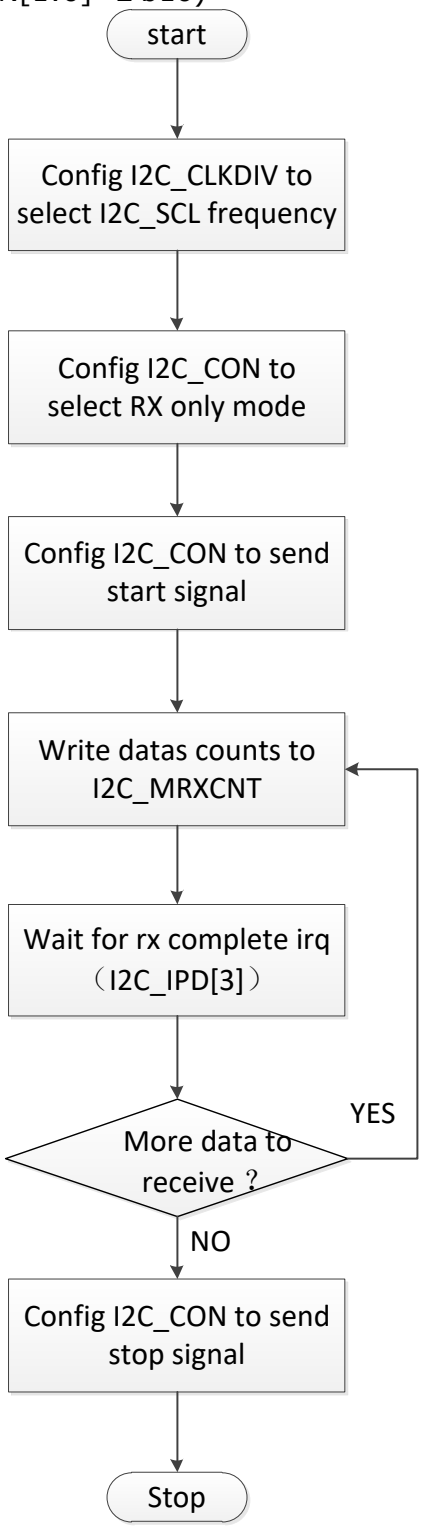

Fig. 21-7 I2C Flow chat for receive only mode

Copyright 2022 © Rockchip Electronics Co., Ltd.

- Mix mode (I2C_CON[1:0]=2'b01 or I2C_CON[1:0]=2'b11)

# Chapter 22 I2S

## 22.1 Overview

The I2S/PCM/TDM controller is designed for interfacing between the AHB bus and the I2S bus.
The I2S bus (Inter-IC sound bus) is a serial link for digital audio data transfer between devices in the system and is invented by Philips Semiconductor. Now it is widely used by many semiconductor manufacturers.
I2S bus is widely used in the devices such as ADC, DAC, DSP, CPU, etc. With the I2S interface, we can connect audio devices and the embedded SoC platform together and provide an audio interface solution for the system.

### 22.1.1 Features

There are nine I2S/PCM/TDM controllers and two I2S/PCM controllers embed in the system. I2S/PCM/TDM controllers support I2S format, PCM format and TDM format. While I2S/PCM controllers only support I2S format and PCM format. The nine I2S/PCM/TDM controllers are I2S0, I2S1, I2S4, I2S5, I2S6, I2S7, I2S8, I2S9 and I2S10. Remaining two I2S/PCM controllers are 2-channel I2S2 and I2S3.
Unless stated separately, all of the following features apply to I2S0~I2S10.

- Support eight internal 32-bit wide and 32-location deep FIFOs, four for transmitting and the others for receiving audio data for I2S0 and I2S1
- Support two internal 32-bit wide and 32-location deep FIFOs, one for transmitting and the other for receiving audio data for each I2S2 and I2S3
- Support four internal 32-bit wide and 32-location deep transmitting FIFOs for I2S4, I2S5, I2S6 and I2S8
- Support four internal 32-bit wide and 32-location deep receiving FIFOs for I2S7, I2S9 and I2S10
- Support AHB bus interface
- Support 16~32 bits audio data transfer
- Support master and slave mode for I2S0, I2S1, I2S2 and I2S3
- Support only master TX mode for I2S4, I2S5, I2S6 and I2S8
- Support only slave RX mode for I2S7, I2S9 and I2S10
- Support DMA handshaking interface and configurable DMA water level
- Support transmit FIFO empty, underflow, receive FIFO full, overflow interrupt and all interrupts can be masked
- Support configurable water level of transmit FIFO empty and receive FIFO full interrupt
- Support combined interrupt output
- Support 2-channel audio transmitting and receiving in PCM mode for I2S0, I2S1, I2S2 and I2S3
- Support 2-channel audio transmitting in PCM mode for I2S4, I2S5, I2S6 and I2S8
- Support 2-channel audio receiving in PCM mode for I2S7, I2S9 and I2S10
- Support 8-channel audio transmitting and receiving in I2S mode for I2S0 and I2S1
- Support 2-channel audio transmitting and receiving in I2S mode for I2S2 and I2S3
- Support 8-channel audio transmitting in I2S mode for I2S4, I2S5, I2S6 and I2S8
- Support 8-channel audio receiving in I2S mode for I2S7, I2S9 and I2S10
- Support up to 16-channel audio transmitting and receiving in TDM mode for I2S/PCM/TDM controllers
- Support up to 192kHz sample rate for I2S0, I2S1, I2S2, I2S3, I2S4 and I2S8
- Support up to 768kHz sample rate for I2S5, I2S6, I2S7, I2S9 and I2S10
- Support I2S normal, left and right justified mode serial audio data transfer
- Support PCM early, late1, late2, late3 mode serial audio data transfer
- Support TDM normal, 1/2 cycle left shift , 1 cycle left shift, 2 cycle left shift, right shift mode serial audio data transfer for I2S/PCM/TDM controllers
- Support MSB or LSB first serial audio data transfer
- Support 16 to 31 bit audio data left or right justified in 32-bit wide FIFO

Copyright 2022 © Rockchip Electronics Co., Ltd.

- Support two 16-bit audio data store together in one 32-bit wide location
- Support configurable SCLK and LRCK polarity
- Support a range of 16 to 32 programmable slot bit width in TDM mode for I2S/PCM/TDM controllers
- Support a range of 32 to 512 programmable frame width in TDM mode for I2S/PCM/TDM controllers
- Support a range of 32 to 256 programmable frame width in I2S/PCM mode for I2S/PCM/TDM controllers and I2S/PCM controllers except I2S4 and I2S8
- Support a range of 32 to 512 programmable frame width in I2S/PCM mode for I2S4 and I2S8

## 22.2 Block Diagram

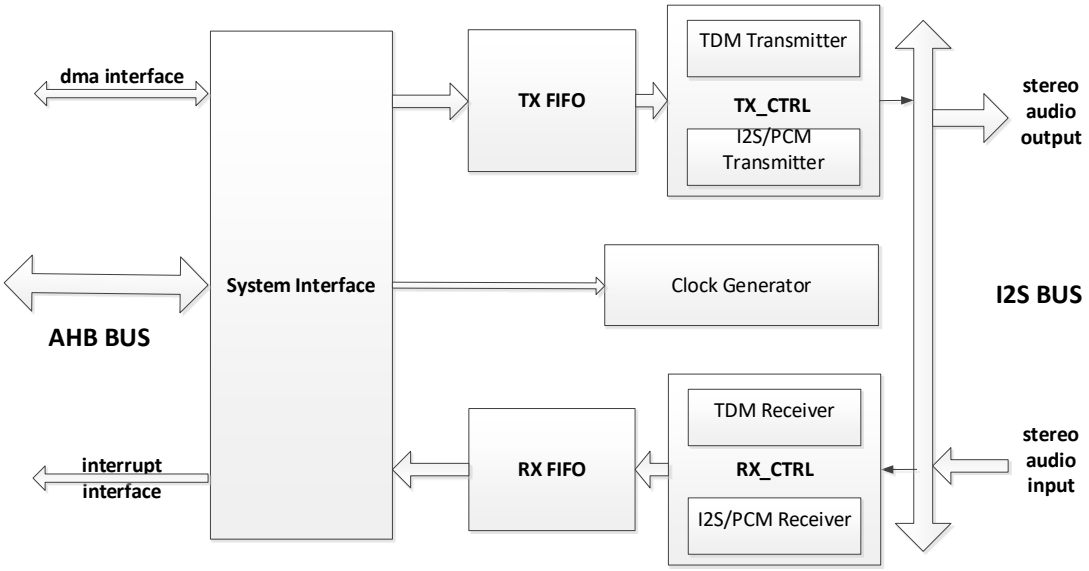

Fig. 22-1 I2S/PCM/TDM Controller (8-channel) Block Diagram

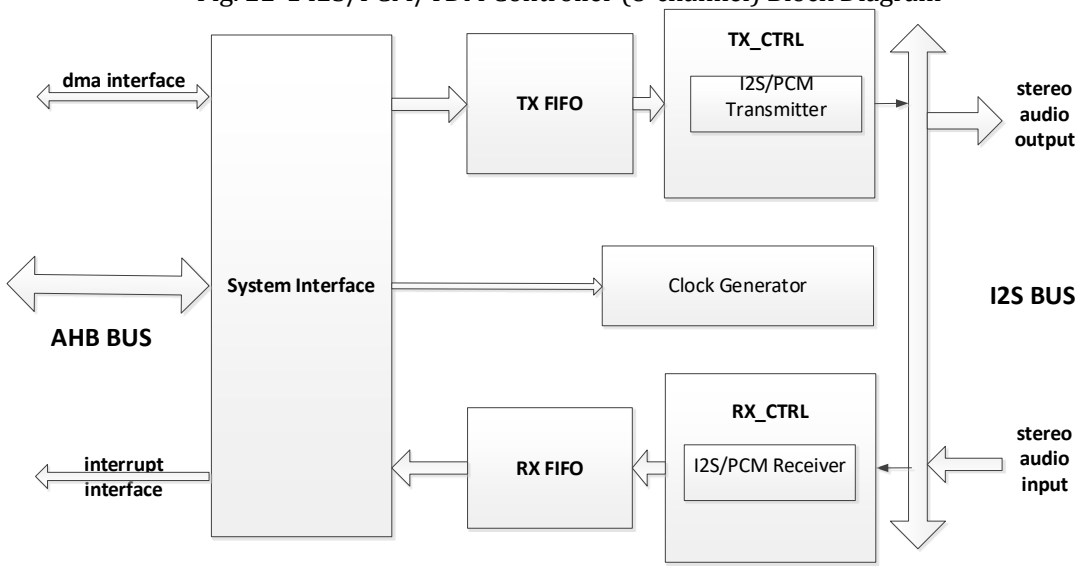

Fig. 22-2 I2S/PCM Controller (2-channel) Block Diagram

**System Interface**

The system interface implements the AHB slave operation. It contains not only control registers of transmitters and receiver inside but also interrupt and DMA handshaking interface.

**Clock Generator**

The Clock Generator implements clock generation function. By the divider of the module, the clock generator generates SCLK and LRCK to transmitter and receiver.

**TX_CTRL**

For I2S/PCM/TDM Controller, TX_CTRL includes TDM transmitter and I2S/PCM transmitter. While for I2S/PCM Controller, TX_CTRL only includes I2S/PCM transmitter. The Transmitters

implement transmission operation. The transmitters can act as either a master or a slave, with I2S, PCM or TDM mode surround serial audio interface.

**RX_CTRL**

For I2S/PCM/TDM Controller, RX_CTRL includes TDM receiver and I2S/PCM receiver. While for I2S/PCM Controller, RX_CTRL only includes I2S/PCM receiver. The Receiver implements receive operation. The receiver can act as either a master or a slave, with I2S, PCM or TDM mode stereo serial audio interface.

**TX FIFO**

The transmit FIFO is the buffer to store transmitted audio data. The size of one FIFO is 32bits x 32.

**RX FIFO**

The receive FIFO is the buffer to store received audio data. The size of one FIFO is 32bits x 32.

## 22.3 Function description

In the I2S/PCM/TDM or I2S/PCM controller, there are four types: transmitter-master & receiver-master; transmitter-master & receiver-slave; transmitter-slave & receiver-master; transmitter-slave & receiver-slave.

In broadcasting application, the I2S/PCM/TDM or I2S/PCM controller is used as a transmitter and external or internal audio CODEC is used as a receiver. In recording application, the I2S/PCM/TDM or I2S/PCM controller is used as a receiver and external or internal audio CODEC is used as a transmitter. Either the I2S/PCM/TDM or I2S/PCM controller or the audio CODEC can act as a master or a slave, but if one is master, the other must be slave.

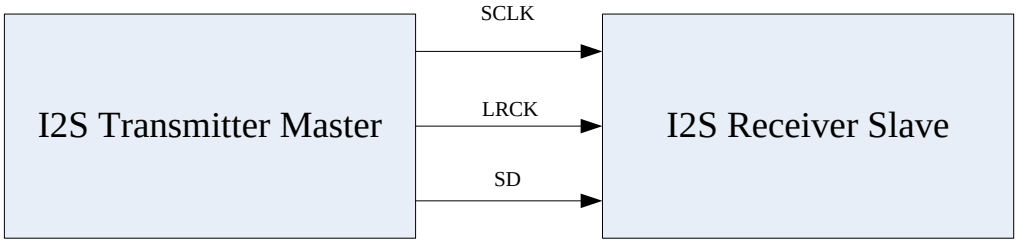

Fig. 22-3 I2S Transmitter-Master & Receiver-Slave Condition

When the transmitter acts as a master, it sends all signals to the receiver (the slave), and CPU controls when to send clock and data to the receiver. When acts as a slave, SD signal still goes from transmitter to receiver, but SCLK and LRCK signals are from the receiver (the master) to the transmitter. Based on three interface specifications, transmitting data should be ready before transmitter receives SCLK and LRCK signals. CPU should know when the receiver to initialize a transaction and when the transmitter to send data.

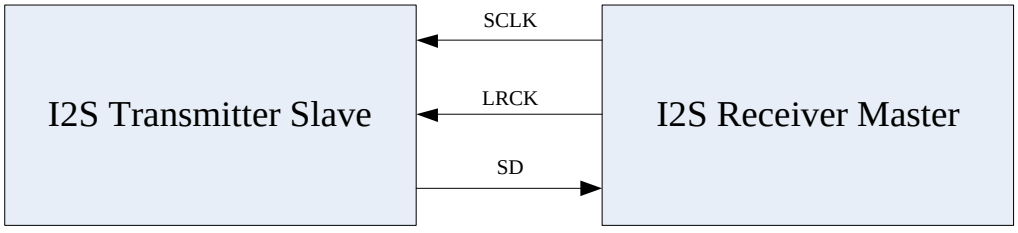

Fig. 22-4 I2S Transmitter-Slave & Receiver-Master Condition

When the receiver acts as a master, it sends SCLK and LRCK signals to the transmitter (the slave) and receives serial data. So CPU must tell the transmitter when to start a transaction for it to prepare transmitting data then start a transfer and send clock and channel-select signals. When the receiver acts as a slave, CPU should only do initial setting and wait for all signals and then start reading data.

Before transmitting or receiving data, CPU need do initial setting to the I2S register. These includes CPU settings, I2S interface registers settings, and maybe the embedded SoC platform settings. These registers must be set before starting data transfer.

### 22.3.1 I2S Normal Mode

This is the waveform of I2S normal mode. For LRCK (i2s_lrck) signal, it goes low to indicate left channel and high to right channel. For SD (i2s_sdo, i2s_sdi) signal, it starts sending the first bit (MSB or LSB) one SCLK clock cycle after LRCK changes. The range of SD signal width is from 16 to 32bits.

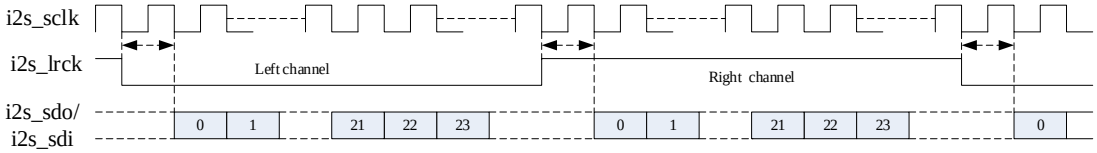

Fig. 22-5 I2S Normal Mode Timing Format

### 22.3.2 I2S Left Justified Mode

This is the waveform of I2S left justified mode. For LRCK (i2s_lrck) signal, it goes high to indicate left channel and low to right channel. For SD (i2s_sdo, i2s_sdi) signal, it starts sending the first bit (MSB or LSB) at the same time when LRCK changes. The range of SD signal width is from 16 to 32bits.

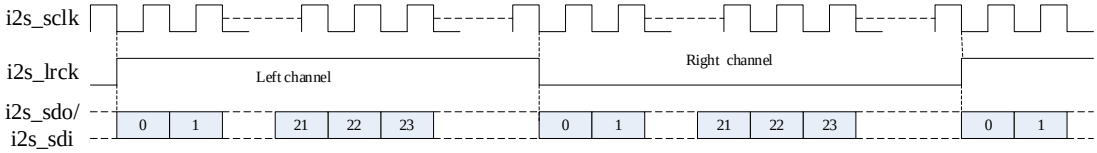

Fig. 22-6 I2S Left Justified Mode Timing Format

### 22.3.3 I2S Right Justified Mode

This is the waveform of I2S right justified mode. For LRCK (i2s_lrck) signal, it goes high to indicate left channel and low to right channel. For SD (i2s_sdo, i2s_sdi) signal, it transfers MSB or LSB first; but what is different from I2S normal or left justified mode, the last bit of the transferred data is aligned to the transition edge of the LRCK signal while one bit is transferred at one SCLK cycle. The range of SD signal width is from 16 to 32bits.

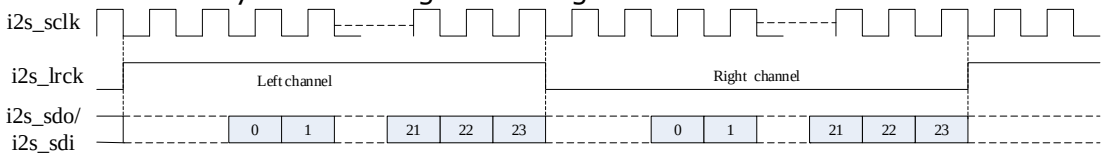

Fig. 22-7 I2S Right Justified Mode Timing Format

### 22.3.4 PCM Early Mode

This is the waveform of PCM early mode. For LRCK (i2s_lrck) signal, it goes high to indicate the start of a group of audio channels. For SD (i2s_sdo, i2s_sdi) signal, it sends the first bit (MSB or LSB) at the same time when LRCK goes high. The range of SD signal width is from 16 to 32bits.

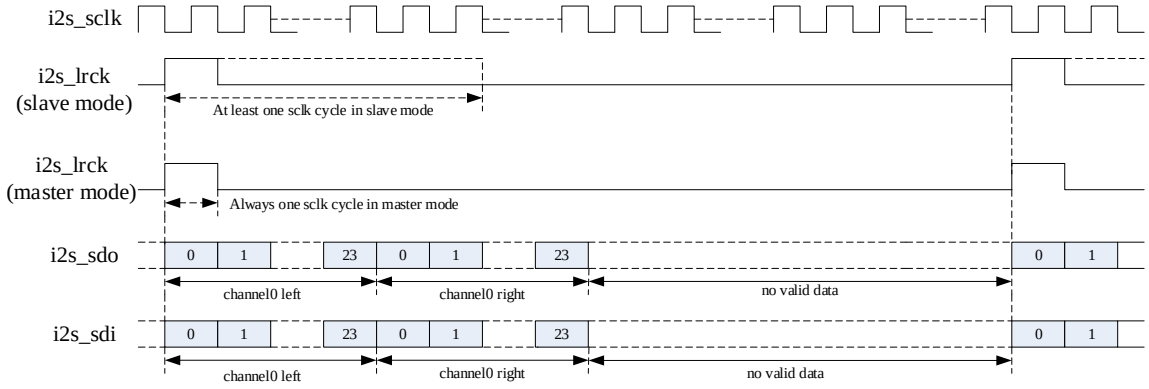

Fig. 22-8 PCM Early Mode Timing Format

### 22.3.5 PCM Late1 Mode

This is the waveform of PCM early mode. For LRCK (i2s_lrck) signal, it goes high to indicate

the start of a group of audio channels. For SD (i2s_sdo, i2s_sdi) signal, it sends the first bit (MSB or LSB) one SCLK clock cycle after LRCK goes high. The range of SD signal width is from 16 to 32bits.

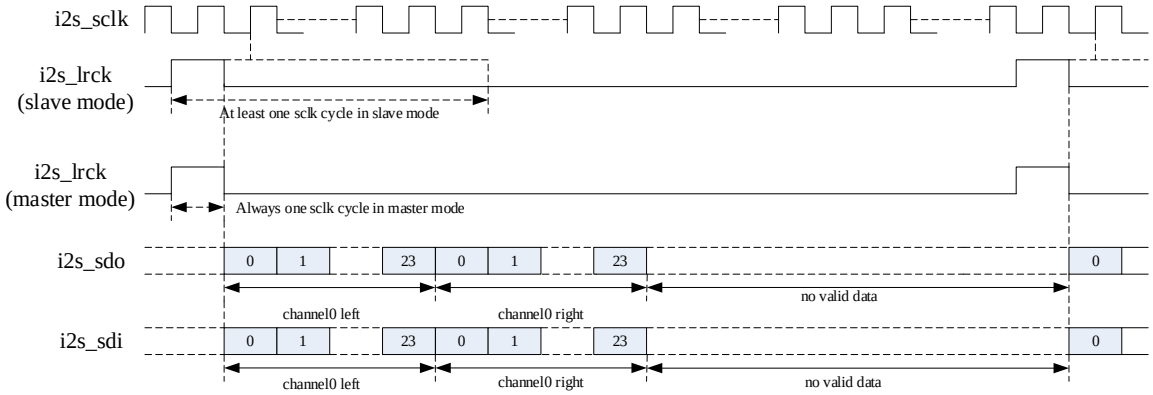

Fig. 22-9 PCM Late1 Mode Timing Format

## 22.3.6 PCM Late2 Mode

This is the waveform of PCM early mode. For LRCK (i2s_lrck) signal, it goes high to indicate the start of a group of audio channels. For SD (i2s_sdo, i2s_sdi) signal, it sends the first bit(MSB or LSB) two SCLK clock cycles after LRCK goes high. The range of SD signal width is from 16 to 32bits.

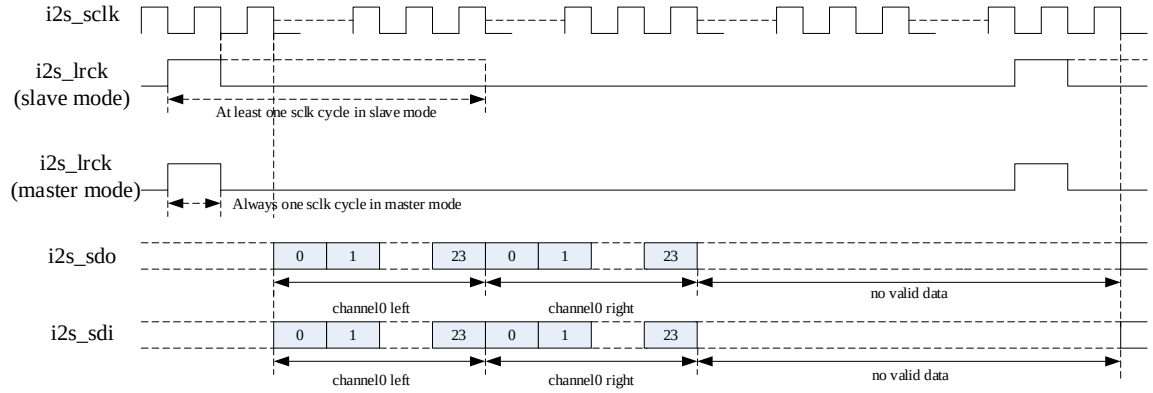

Fig. 22-10 PCM Late2 Mode Timing Format

## 22.3.7 PCM Late3 Mode

This is the waveform of PCM early mode. For LRCK (i2s_lrck) signal, it goes high to indicate the start of a group of audio channels. For SD (i2s_sdo, i2s_sdi) signal, it sends the first bit (MSB or LSB) three SCLK clock cycles after LRCK goes high. The range of SD signal width is from 16 to 32bits.

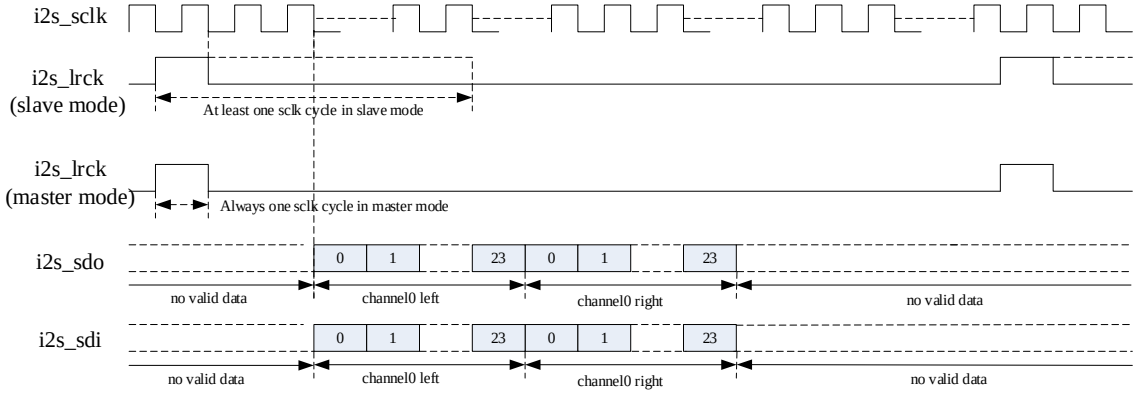

Fig. 22-11 PCM Late3 Mode Timing Format

## 22.3.8 TDM Normal Mode (PCM Format)

This is the waveform of TDM normal mode. For LRCK (i2s_lrck) signal, it goes high to indicate the start of a group of audio channels. For SD (i2s_sdo, i2s_sdi) signal, it sends the first bit (MSB or LSB) on the second falling edge of SCLK after LRCK goes high. The range of SD signal width is from 16 to 32bits.

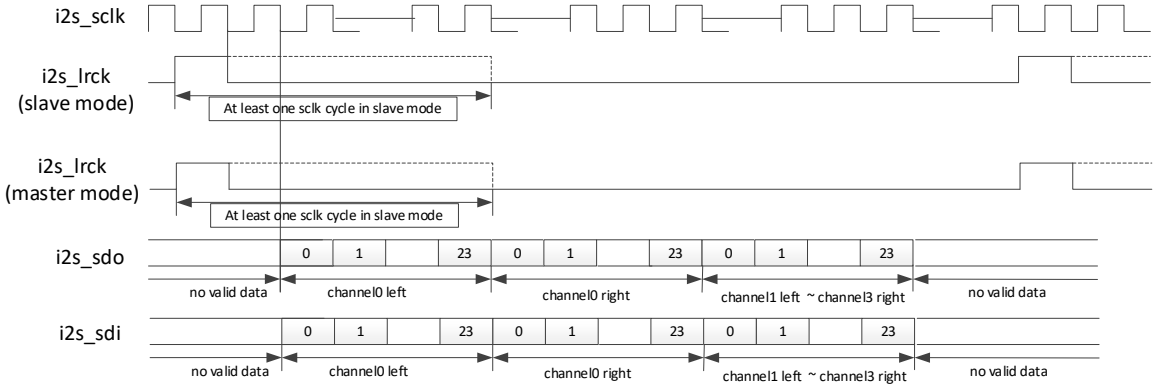

Fig. 22-12 TDM Normal Mode Timing Format (PCM Format)

## 22.3.9 TDM Left Shift Mode0 (PCM Format)

This is the waveform of PCM early mode. For LRCK (i2s_lrck) signal, it goes high to indicate the start of a group of audio channels. For SD (i2s_sdo, i2s_sdi) signal, it sends the first bit (MSB or LSB) on the second rising edge of SCLK after LRCK goes high. The range of SD signal width is from 16 to 32bits.

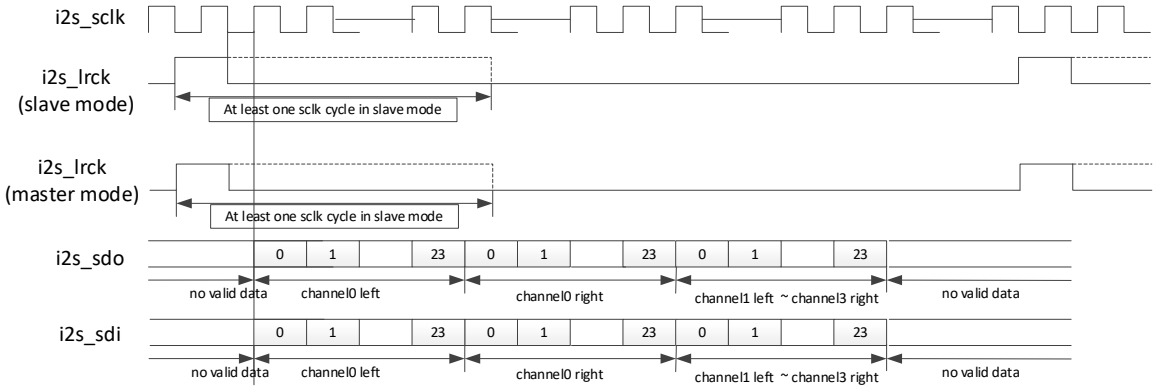

Fig. 22-13 TDM Left Shift Mode 0 Timing Format (PCM Format)

## 22.3.10 TDM Left Shift Mode1 (PCM Format)

This is the waveform of PCM early mode. For LRCK (i2s_lrck) signal, it goes high to indicate the start of a group of audio channels. For SD (i2s_sdo, i2s_sdi) signal, it sends the first bit (MSB or LSB) on the first falling edge of SCLK after LRCK goes high. The range of SD signal width is from 16 to 32bits.

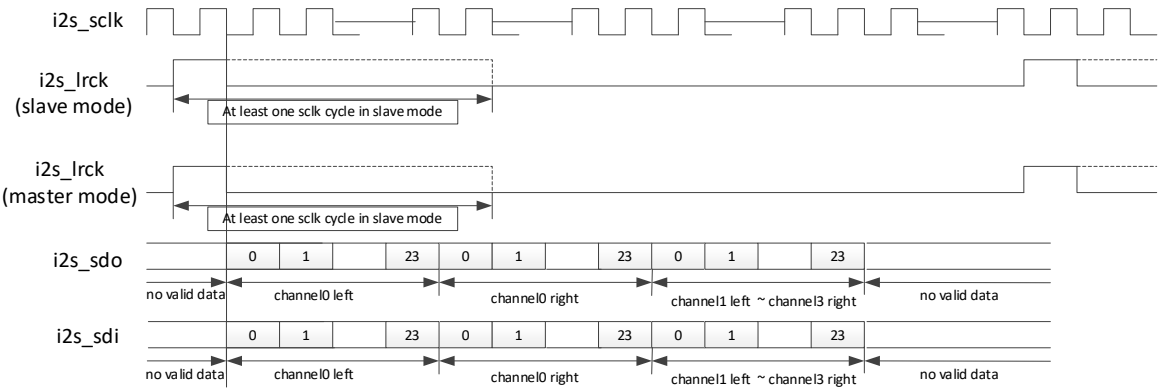

Fig. 22-14 TDM Left Shift Mode 1 Timing Format (PCM Format)

Copyright 2022 © Rockchip Electronics Co., Ltd. 

## 22.3.11 TDM Left Shift Mode2 (PCM Format)

This is the waveform of PCM early mode. For LRCK (i2s_lrck) signal, it goes high to indicate the start of a group of audio channels. For SD (i2s_sdo, i2s_sdi) signal, it sends the first bit (MSB or LSB) on the first rising edge of SCLK after LRCK goes high. The range of SD signal width is from 16 to 32bits.

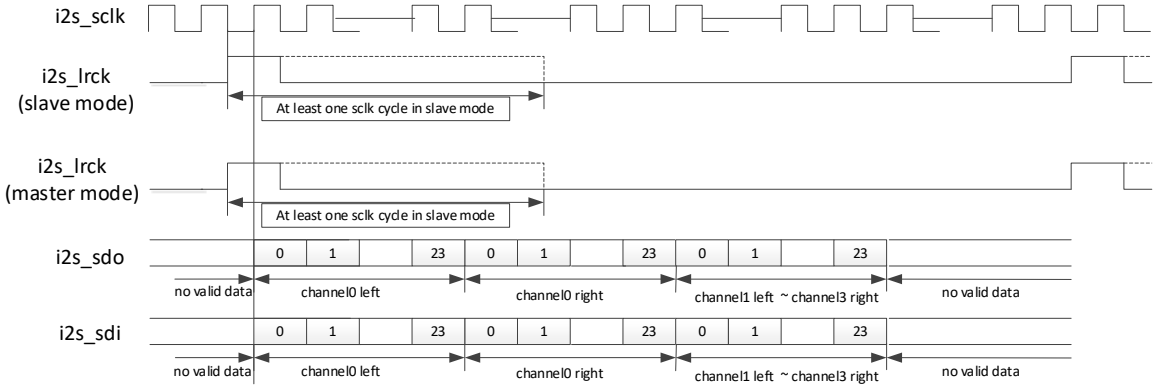

Fig. 22-15 TDM Left Shift Mode 2 Timing Format (PCM Format)

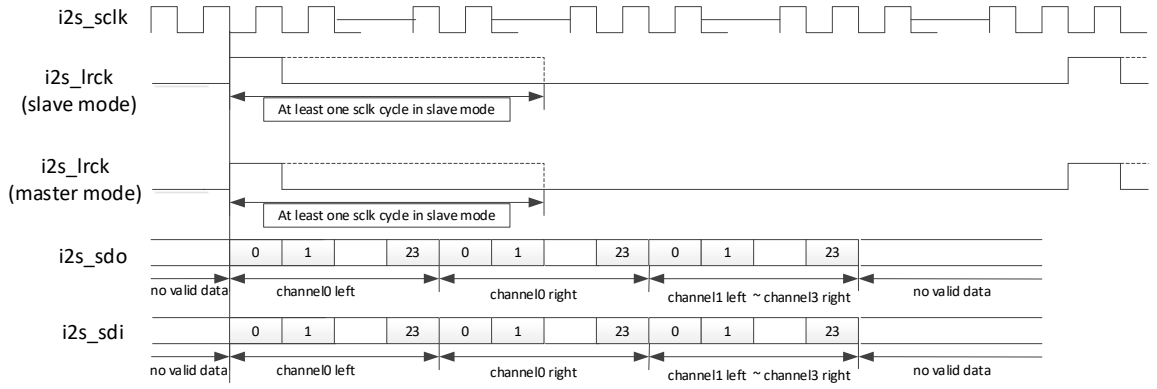
## 22.3.12 TDM Left Shift Mode3 (PCM Format)

This is the waveform of PCM early mode. For LRCK (i2s1_lrck) signal, it goes high to indicate the start of a group of audio channels. For SD (i2s_sdo, i2s_sdi) signal, it sends the first bit (MSB or LSB) at the same time when LRCK goes high. The range of SD signal width is from 16 to 32bits.



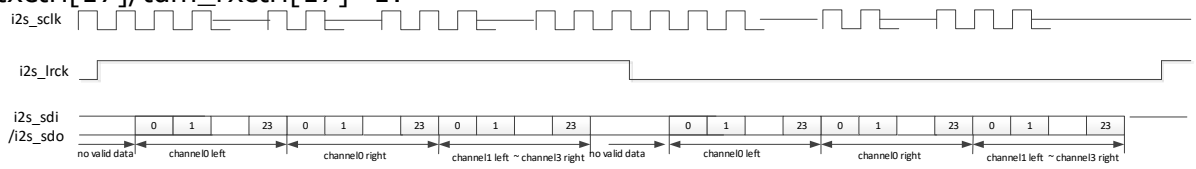


Fig. 22-16 TDM Left Shift Mode 3 Timing Format (PCM Format)

## 22.3.13 TDM Normal Mode (I2S Format)

This is the waveform of I2S normal mode. For SD (i2s_sdo, i2s_sdi) signal, it starts sending the first bit (MSB or LSB)on the first falling edge of SCLK after LRCK changes. The range of SD signal width is from 16 to 32bits.

### 22.3.14 TDM Left Justified Mode (I2S Format)

This is the waveform of I2S left justified mode. For SD (i2s_sdo, i2s_sdi) signal, it starts sending the first bit (MSB or LSB) at the same time when LRCK changes. The range of SD signal width is from 16 to 32bits.

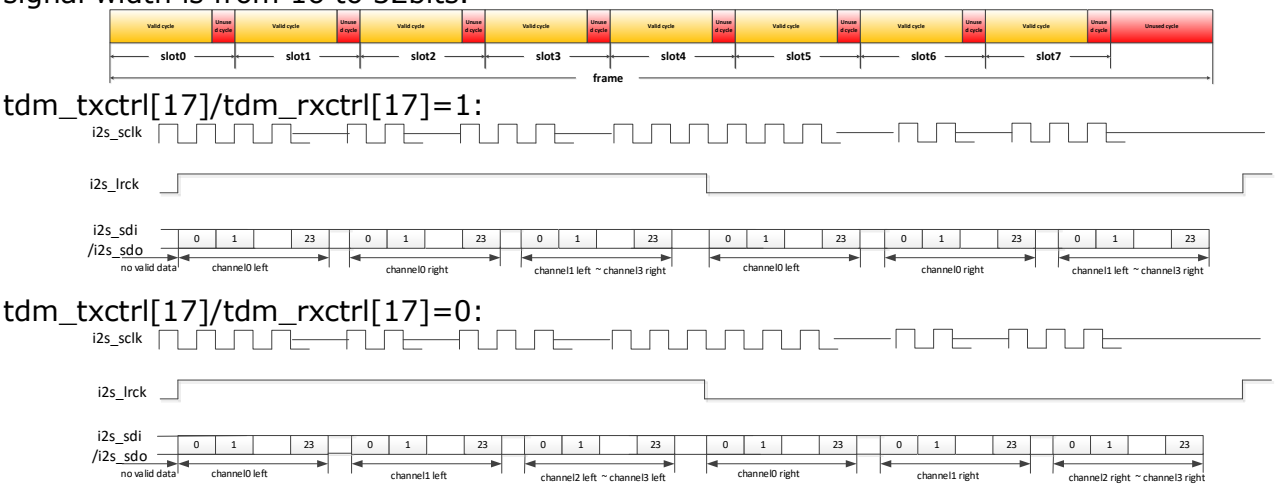

Fig. 22-18 TDM Left Justified Mode Timing Format (I2S Format)

### 22.3.15 TDM Right Justified Mode (I2S Format)

This is the waveform of I2S right justified mode. For SD (i2s_sdo, i2s_sdi) signal, it transfers MSB or LSB first; but what is different from I2S normal or left justified mode. The range of SD signal width is from 16 to 32bits.

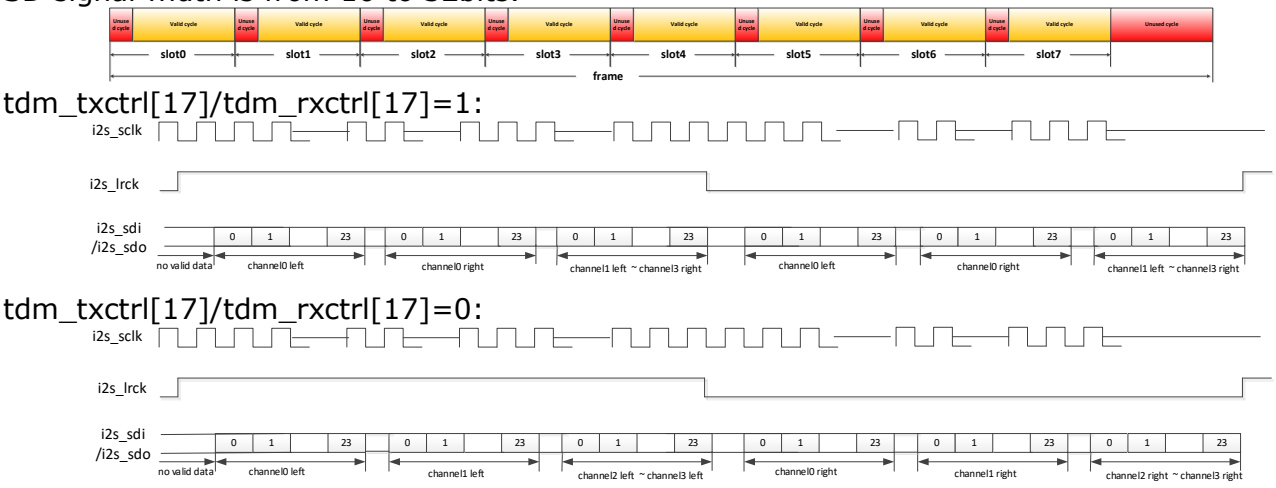

Fig. 22-19 TDM Right Justified Mode Timing Format (I2S Format)

## 22.4 Register description

### 22.4.1 Internal Address Mapping

Slave address can be divided into different length for different usage, which is shown as follows.

### 22.4.2 Registers Summary for I2S/PCM controllers

Following register summary can be applied to I2S0, I2S1, I2S5, I2S6, I2S7, I2S9 and I2S10.

| Name | Offset | Size | Reset Value | Description |
|---|---|---|---|---|
| I2S_2CH_TXCR | 0x0000 | W | 0x0000000F | Transmit Operation Control Register |

| Name | Offset | Size | Reset Value | Description |
|---|---|---|---|---|
| I2S_2CH_RXCR | 0x0004 | W | 0x0000000F | Receive Operation Control Register |
| I2S_2CH_CKR | 0x0008 | W | 0x00071F1F | Clock Generation Register |
| I2S_2CH_TXFIFOLR | 0x000C | W | 0x00000000 | TX FIFO Level Register |
| I2S_2CH_DMACR | 0x0010 | W | 0x001F0000 | DMA Control Register |
| I2S_2CH_INTCR | 0x0014 | W | 0x01F00000 | Interrupt Control Register |
| I2S_2CH_INTSR | 0x0018 | W | 0x00000000 | Interrupt Status Register |
| I2S_2CH_XFER | 0x001C | W | 0x00000000 | Transfer Start Register |
| I2S_2CH_CLR | 0x0020 | W | 0x00000000 | SCLK Domain Logic Clear Register |
| I2S_2CH_TXDR | 0x0024 | W | 0x00000000 | Transmit FIFO Data Register |
| I2S_2CH_RXDR | 0x0028 | W | 0x00000000 | Receive FIFO Data Register |
| I2S_2CH_RXFIFOLR | 0x002C | W | 0x00000000 | RX FIFO Level Register |
| I2S_2CH_VERSION | 0x0030 | W | 0x20150001 | Version Register |

*Notes:Size:**B**- Byte (8 bits) access, **HW**- Half WORD (16 bits) access, **W**-WORD (32 bits) access, **DW**-Double WORD (64 bits) access*

## 22.4.4 Registers Summary for I2S/PCM/TDM controllers Part 1

Following register summary can be applied to I2S0, I2S1, I2S5, I2S6, I2S7, I2S9 and I2S10. Note that for I2S5 and I2S6, only TX is used, RX related registers should be ignored. For I2S7, I2S9 and I2S10, only RX is used, TX related registers should be ignored.

## 22.4.6 Registers Summary for I2S/PCM/TDM controllers Part 2

For I2S4 and I2S8, only master TX mode is used, RX related registers should be ignored. Registers of I2S4 and I2S8 are same as I2S0, I2S1, I2S5, I2S6, I2S7, I2S9 and I2S10 except that I2S_TDM_8CH_CKR is different.

| Name | Offset | Size | Reset Value | Description |
|---|---|---|---|---|
| I2S_TDM_8CH_CKR | 0x0000 | W | 0x00003e1f | Clock Generation Register |

## 22.4.7 Detail Registers Description

There are 2 IOMUX groups connected to I2S2. BUS_IOC_GPIO3B_IOMUX_SEL_H[3:0], BUS_IOC_GPIO3B_IOMUX_SEL_H[7:4], BUS_IOC_GPIO3B_IOMUX_SEL_L[3:0], BUS_IOC_GPIO3B_IOMUX_SEL_H[11:8], BUS_IOC_GPIO3B_IOMUX_SEL_L[7:4] and BUS_IOC_GPIO3B_IOMUX_SEL_L[11:8] are used to select whether I2S2 group 0 interface or group 1 interface is used.

## 22.5.4 I2S3 Interface Description

The following table shows the I2S3 interface description.

Copyright 2022 © Rockchip Electronics Co., Ltd.

Table 22-6 I2S3 Interface Description

| Module Pin | Direction | Pad Name | IOMUX Setting |
|---|---|---|---|
| i2s3_mclk | I/O | GMAC1_TXD2/SDIO_D0_M1/I2S3_MCLK/FSPI_D0_M2/I2C6_SDA_M4/PWM10_M0/SPI4_MISO_M1/GPIO3_A0_u | BUS_IOC_GPIO3A_IOMUX_SEL_L[3:0]=4'h3 |
| i2s3_sclk | I/O | GMAC1_TXD3/SDIO_D1_M1/I2S3_SCLK/AUDDSM_LN/FSPI_D1_M2/I2C6_SCL_M4/PWM11_IR_M0/SPI4_MOSI_M1/GPIO3_A1_u | BUS_IOC_GPIO3A_IOMUX_SEL_L[7:4]=4'h3 && SYS_GRF_SOC_CON6[8]=1'b1 |
| i2s3_lrck | I/O | GMAC1_RXD2/SDIO_D2_M1/I2S3_LRCK/AUDDSM_LP/FSPI_D2_M2/UART8_TX_M1/SPI4_CLK_M1/GPIO3_A2_u | BUS_IOC_GPIO3A_IOMUX_SEL_L[11:8]=4'h3 && SYS_GRF_SOC_CON6[9]=1'b1 |
| i2s3_sdo0 | O | GMAC1_RXD3/SDIO_D3_M1/I2S3_SDO/AUDDSM_RN/FSPI_D3_M2/UART8_RX_M1/SPI4_CS0_M1/GPIO3_A3_u | BUS_IOC_GPIO3A_IOMUX_SEL_L[15:12]=4'h3 |
| i2s3_sdi0 | I | GMAC1_TXCLK/SDIO_CMD_M1/I2S3_SDI/AUDDSM_RP/UART8_RTSN_M1/SPI4_CS1_M1/GPIO3_A4_d | BUS_IOC_GPIO3A_IOMUX_SEL_H[3:0]=4'h3 |

The TX interface of I2S3 can be also connected to the RX interface of Digital Audio Codec by programming SYS_GRF_SOC_CON6[11]. If SYS_GRF_SOC_CON6[11] is 1'b1, I2S3 is connected to Digital Audio Codec.

### 22.5.5 I2S4 and I2S8 Interface Description

I2S4 and I2S8 are connected to DPTX0 and DPTX1 respectively. I2S4 and I2S8 should be always operate in master TX mode, other modes are not support. Following table shows connection between I2S4/8 and DPTX0/1.

Table 22-7 I2S4/8 and DPTX0/1 Interface Description

| Module Pin (I2S4/8) | Direction | Module Pin (DPTX0/1) |
|---|---|---|
| i2sx_sclk(x=4,8) | O | i2sclk |
| i2sx_lrck(x=4,8) | O | i2slrclk_i |
| i2sx_sdo[3:0] (x=4,8) | O | i2sdata_i[3:0] |

### 22.5.6 I2S5 and I2S6 Interface Description

The TX interface of I2S5 can be connected to EDP TX Controller0 and HDMI TX Controller0 at the same time by programming VO1_GRF_VO1_CON0[3] to 1'b1 and VO1_GRF_VO1_CON3[13] to 1'b1 respectively. Note that I2S5 should always operate in master TX mode, other modes are not support.

The TX interface of I2S6 can be connected to EDP TX Controller1 and HDMI TX Controller1 at the same time by programming VO1_GRF_VO1_CON1[3] to 1'b1 and VO1_GRF_VO1_CON6[13] to 1'b1 respectively. Note that I2S6 should always operate in master TX mode, other modes are not support.

Following table shows connection between I2S5/6 and EDP TX Controller0/1.

Table 22-8 I2S5/6 and EDP TX Controller0/1 Interface Description

| Module Pin (I2S5/6) | Direction | Module Pin (EDP TX Controller0/1) |
|---|---|---|
| i2sx_sclk(x=5,6) | O | I_I2S_SCK_IN |
| i2sx_lrck(x=5,6) | O | I_I2S_WS_IN |
| i2sx_sdo0 (x=5,6) | O | I_I2S_SD0_IN |
| i2sx_sdo1 (x=5,6) | O | I_I2S_SD1_IN |
| i2sx_sdo2 (x=5,6) | O | I_I2S_SD2_IN |
| i2sx_sdo3 (x=5,6) | O | I_I2S_SD3_IN |

Copyright 2022 © Rockchip Electronics Co., Ltd.

Table 22-9 I2S5/6 and HDMI TX Controller0/1 Interface Description

| Module Pin (I2S5/6) | Direction | Module Pin (HDMI TX Controller0/1) |
|---|---|---|

## 22.6 Application Notes

### 22.6.1 Software Application Notes

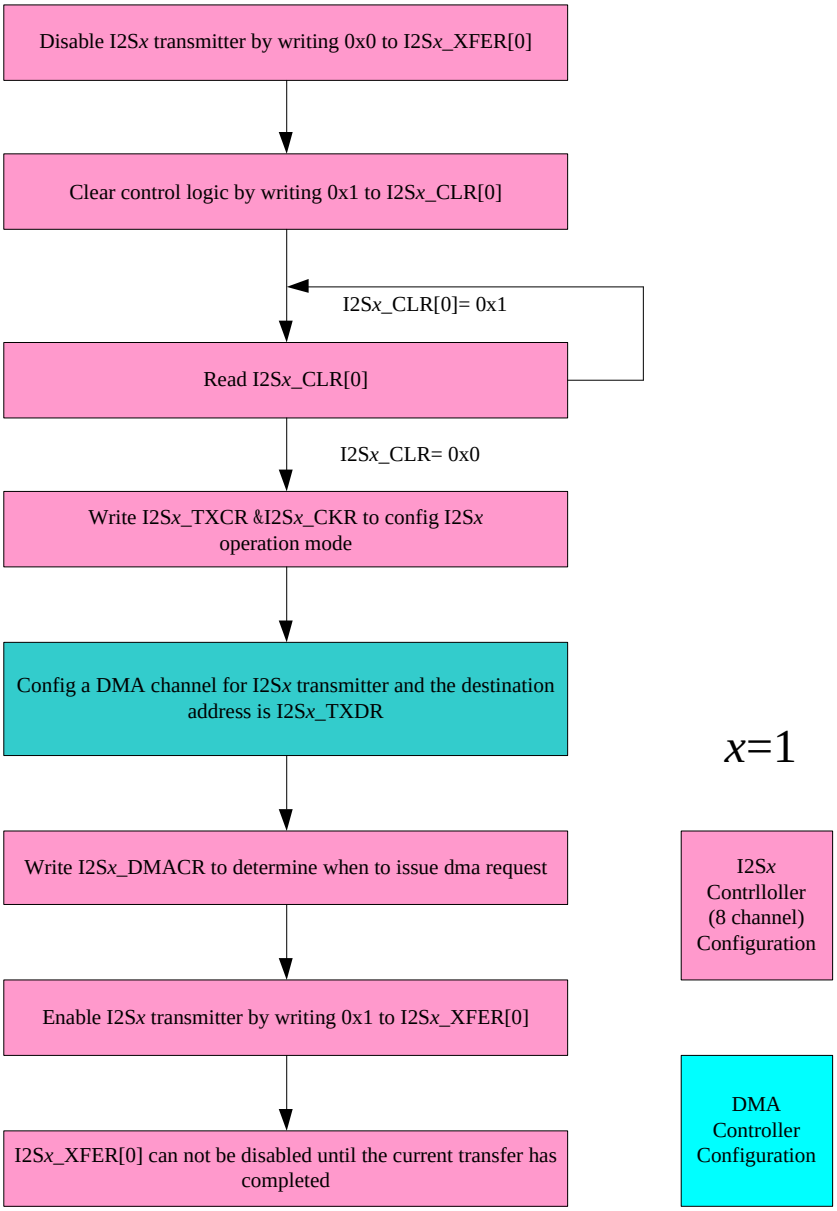

Fig. 22-20 I2S/PCM/TDM Controller Transmit Operation Flow Chart

*Note: User should clear TX/RX logical by CLR[0]/CLR[1] and wait clear operation done before configure the other registers.*

For I2S0, I2S1, I2S4, I2S5, I2S6, I2S7, I2S8, I2S9 and I2S10, these are I2S/PCM/TDM controllers. I2S/PCM/TDM controllers can support up to 16 channels when operate in TDM mode. Following configurations must be observed when in 16-channel TDM mode before starting sending or receiving audio data.

1. Set I2S_TDM_8CH_TXCR.TFS to 2'b11 or I2S_TDM_8CH_RXCR.TFS to 2'b11.
2. Set I2S_TDM_8CH_TDM_TXCTRL.TX_TDM_FSYNC_WIDTH_SEL0 to 1'b1 or I2S_TDM_8CH_TDM_RXCTRL.RX_TDM_FSYNC_WIDTH_SEL0 to 1'b1.
3. Set other registers properly.

# Chapter 23 SPDIF Transmitter

## 23.1 Overview

The SPDIF transmitter is a self-clocking, serial, unidirectional interface for the interconnection of digital audio equipment for consumer and professional applications, using linear PCM coded audio samples.
It provides the basic structure of the interface. Separate documents define items specific to particular applications.
When used in a professional application, the interface is primarily intended to carry monophonic or stereophonic programmes, at a 48 kHz sampling frequency and with a resolution of up to 24bits per sample; it may alternatively be used to carry signals sampled at 32 kHz or 44.1 kHz.
When used in a consumer application, the interface is primarily intended to carry stereophonic programmes, with a resolution of up to 20 bits per sample, an extension to 24 bits per sample being possible.
When used for other purposes, the interface is primarily intended to carry audio data coded other than as linear PCM coded audio samples. Provision is also made to allow the interface to carry data related to computer software or signals coded using non-linear PCM. The format specification for these applications is not part of this standard.
In all cases, the clock references and auxiliary information are transmitted along with the programme.
There are 6 SPDIF transmitters in total. They are SPDIF0, SPDIF1, SPDIF2, SPDIF3, SPDIF4 and SPDIF5.
MCLK is the operation clock of SPDIF transmitter. The maximum frequency of MCLK are different for the 6 SPDIF transmitters. Following table shows the maximum frequency of MCLK for SPDIF0, SPDIF1, SPDIF2, SPDIF3, SPDIF4 and SPDIF5.

Table 23-1 Maximum Frequency of MCLK for the 6 SPDIF Transmitters

| SPDIF transmitter | Maximum frequency of MCLK |
|---|---|
| SPDIF0, SPDIF1 | 49.152MHz |
| SPDIF2, SPDIF5 | 393.216MHz |
| SPDIF3, SPDIF4 | 196.608MHz |

Each SPDIF transmitter supports following features.

- Support one internal 32-bit wide and 32-location deep sample data buffer
- Support two 16-bit audio data store together in one 32-bit wide location
- Support AHB bus interface
- Support biphase format stereo audio data output
- Support DMA handshake interface and configurable DMA water level
- Support sample data buffer empty and block terminate interrupt
- Support combine interrupt output
- Support 16 to 31 bit audio data left or right justified in 32-bit wide sample data buffer
- Support 48, 44.1, 32kHz sample rate
- Support 16, 20, 24 bits audio data transfer

## 23.2 Block Diagram

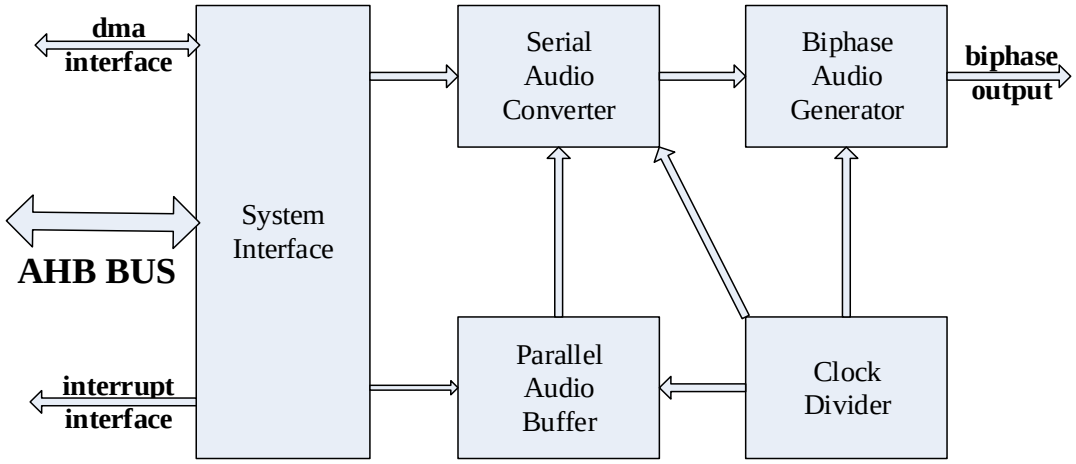

Fig. 23-1 SPDIF transmitter Block Diagram

The SPDIF transmitter is composed of following module.

**System Interface**

The system interface implements the AHB slave operation. It contains not only control registers of transmitters and receiver inside but also interrupt and DMA handshaking interface.

**Clock Divider**

The clock divider implements clock generation function. It divides the source clock MCLK to generate the working clock used for the digital audio data transformation and transmission.

**Parallel Audio Buffer**

The parallel audio buffer stores the audio data to be transmitted. The size of the FIFO is 32bits x 32.

**Serial Audio Converter**

The serial audio converter converts the parallel audio data from the parallel audio buffer to the serial audio data.

**Biphase Audio Generator**

The biphase audio generator reads serial audio data from the serial audio converter and generates biphase audio data based on IEC-60958 standard.

## 23.3 Function description

### 23.3.1 Frame Format

A frame is uniquely composed of two sub-frames. For linear coded audio applications, the rate of transmission of frames corresponds exactly to the source sampling frequency.
In the 2-channel operation mode, the samples taken from both channels are transmitted by time multiplexing in consecutive sub-frames. The first sub-frame(left channel in stereophonic operation and primary channel in monophonic operation) normally use preamble M. However, the preamble is changed to preamble B once every 192 frame to identify the start of the block structure used to organize the channel status information. The second sub-frame (right in stereophonic operation and secondary channel in monophonic operation) always use preamble W.

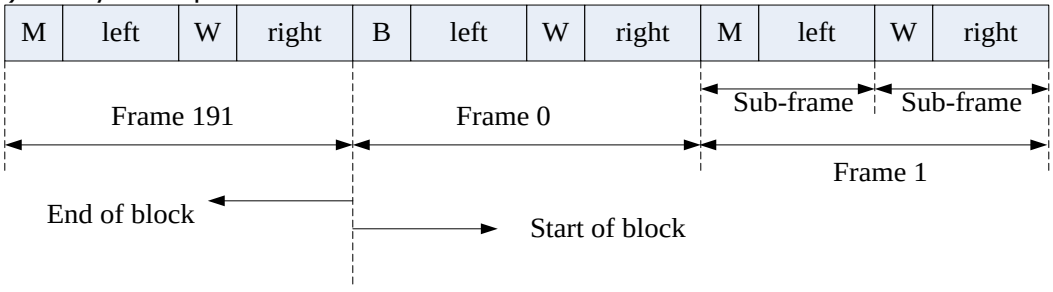

Fig. 23-2 SPDIF Frame Format

In the single channel operation mode in a professional application, the frame format is the

Copyright 2022 © Rockchip Electronics Co., Ltd.

same as in the 2-channel mode. Data is carried only in the first sub-frame and may be duplicated in the second sub-frame. If the second sub-frame is not carrying duplicate data, then time slot 28 (validity flag) shall be set to logical '1' (not valid).

### 23.3.2 Sub-frame Format

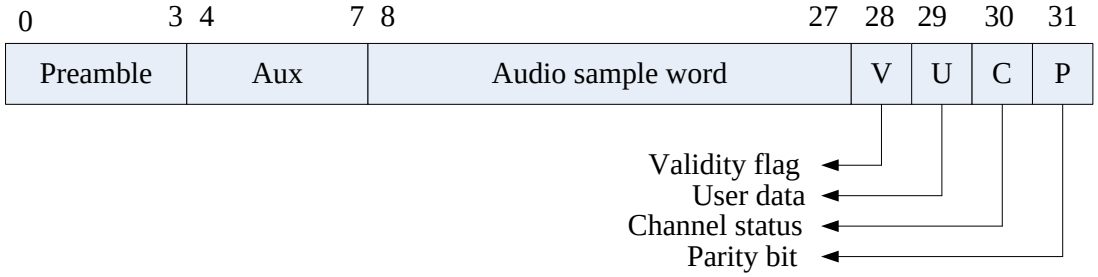

Fig. 23-3 SPDIF Sub-frame Format

Each sub-frame is divided into 32 time slots, numbered from 0 to 31. Time slot 0 to 3 carries one of the three permitted preambles. Time slot 4 to 27 carry the audio sample word in linear 2's complement representation. The MSB is carried by time slot 27. When a 24-bit coding range is used, the LSB is in time slot 4. When a 20-bit coding range is used, time slot 8 to 27 carry the audio sample word with the LSB in time slot 8.Time slot 4 to 7 may be used for other application. Under these circumstances, the bits in the time slot 4 to 7 are designated auxiliary sample bits.

If the source provides fewer bits than the interface allows (either 24 or 20), the unused LSBs are set to a logical '0'. For a non-linear PCM audio application or a data application the main data field may carry any other information. Time slot 28 carries the validity flag associated with the main data field. Time slot 29 carries 1 bit of the user data associated with the audio channel transmitted in the same sub-frame. Time slot 30 carries one bit of the channel status words associated with the main data field channel transmitted in the same sub-frame. Time slot 31 carries a parity bit such that time slots 4 to 31 inclusive carries an even number of ones and an even number of zeros.

### 23.3.3 Channel Coding

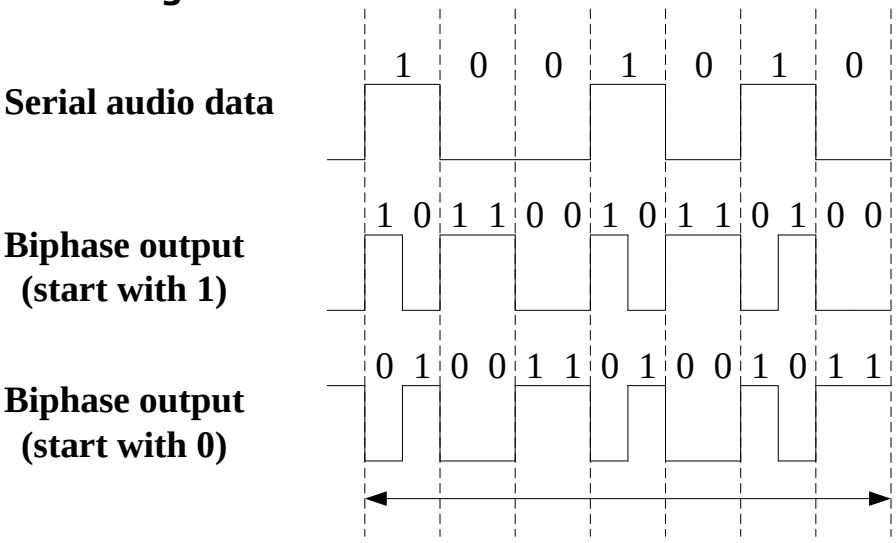

Fig. 23-4 SPDIF Channel Coding

To minimize the direct current component on the transmission line, to facilitate clock recovery from the data stream and to make the interface insensitive to the polarity of connections, time slots 4 to 31 are encoded in biphase-mark.

Each bit to be transmitted is represented by a symbol comprising two consecutive binary states. The first state of a symbol is always different from the second state of the previous symbol. The second state of the symbol is identical to the first if the bit to be transmitted is logical '0'.However, it is different from the first if the bit is logical '1'.

### 23.3.4 Preamble

Preambles are specific patterns providing synchronization and identification of the sub-frames and blocks.

Copyright 2022 © Rockchip Electronics Co., Ltd.

To achieve synchronization within one sampling period and to make this process completely reliable, these patterns violate the biphase-mark code rules, thereby avoiding the possibility of data imitating the preambles.
A set of three preambles is used. These preambles are transmitted in the time allocated to four time slots (time slots 0 to 3) and are represented by eight successive states. The first state of the preamble is always different from the second state of the previous symbol.

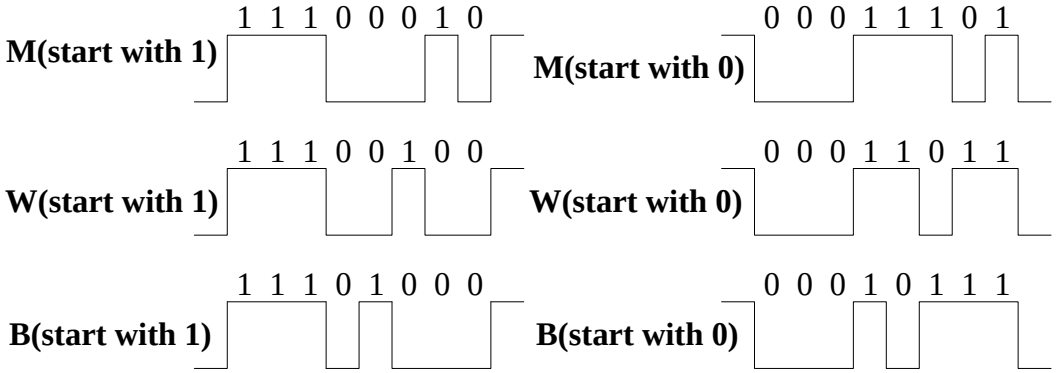

Fig. 23-5 SPDIF Preamble

Like biphase code, these preambles are dc free and provide clock recovery. They differ in at least two states from any valid biphase sequence.

# 23.4 Register Description

## 23.4.1 Registers Summary

| Name | Offset | Size | Reset Value | Description |
|---|---|---|---|---|
| SPDIF_CFGR | 0x0000 | W | 0x00000000 | Transfer Configuration Register |
| SPDIF_SDBLR | 0x0004 | W | 0x00000000 | Sample Date Buffer Level Register |
| SPDIF_DMACR | 0x0008 | W | 0x00000000 | DMA Control Register |
| SPDIF_INTCR | 0x000C | W | 0x00000000 | Interrupt Control Register |
| SPDIF_INTSR | 0x0010 | W | 0x00000000 | Interrupt Status Register |
| SPDIF_XFER | 0x0018 | W | 0x00000000 | Transfer Start Register |
| SPDIF_SMPDR | 0x0020 | W | 0x00000000 | Sample Data Register |
| SPDIF_VLDFRn | 0x0060 | W | 0x00000000 | Validity Flag Register n(n=0~11) |
| SPDIF_USRDRn | 0x0090 | W | 0x00000000 | User Data Register n(n=0~11) |
| SPDIF_CHNSRn | 0x00C0 | W | 0x00000000 | Channel Status Register n(n=0~11) |
| SPDIF_BURTSINFO | 0x0100 | W | 0x00000000 | Channel Burst Info Register |
| SPDIF_REPETTION | 0x0104 | W | 0x00000000 | Channel Repetition Register |
| SPDIF_BURTSINFO_SHD | 0x0108 | W | 0x00000000 | Shadow Channel Burst Info Register |
| SPDIF_REPETTION_SHD | 0x010C | W | 0x00000000 | Shadow Channel Repetition Register |
| SPDIF_USRDR_SHDn | 0x0190 | W | 0x00000000 | Shadow User Data Register n(n=0~11) |
| SPDIF_VERSION | 0x01C0 | W | 0x20160100 | Version Register |

*Notes:Size:**B**- Byte (8 bits) access, **HW**- Half WORD (16 bits) access, **W**-WORD (32 bits) access, **DW**-Double WORD (64 bits) access*

*Notes: I=input, O=output, I/O=input/output, bidirectional*

*The output of SPDIF3 are internally connected to EDP TX Controller0 and HDMI TX Controller0 respectively. The SPDIF audio interface of EDP TX Controller0 and HDMI TX Controller0 can work at the same time. If GRF_VO1_CON0[4] is set 1'b1, then the output of SPDIF3 are connected to*

Copyright 2022 © Rockchip Electronics Co., Ltd. 

*EDP TX Controller0. If GRF_VO1_CON3[14] is set 1'b1, then the output of SPDIF3 are connected to HDMI TX Controller0.*
*The output of SPDIF4 are internally connected to EDP TX Controller1 and HDMI TX Controller1 respectively. The SPDIF audio interface of EDP TX Controller1 and HDMI TX Controller1 can work at the same time. If GRF_VO1_CON1[4] is set 1'b1, then the output of SPDIF4 are connected to EDP TX Controller1. If GRF_VO1_CON6[14] is set 1'b1, then the output of SPDIF3 are connected to HDMI TX Controller1.*
*The output of SPDIF2 are internally connected to DPTX0. DPTX0 SPDIF audio interface operation clock and MCLK of SPDIF2 are from the same source. MCLK of SPDIF2 should be divided by 4 by programming SPDIF_CFGR.MCD to 3 to meet the requirement that DPTX0 SPDIF audio interface operates at 4 times frequency over sample the output of SPDIF2. SPDIF5 is similar with SPDIF2 except that SPDIF5 is connected to DPTX1.*

## 23.6 Application Notes

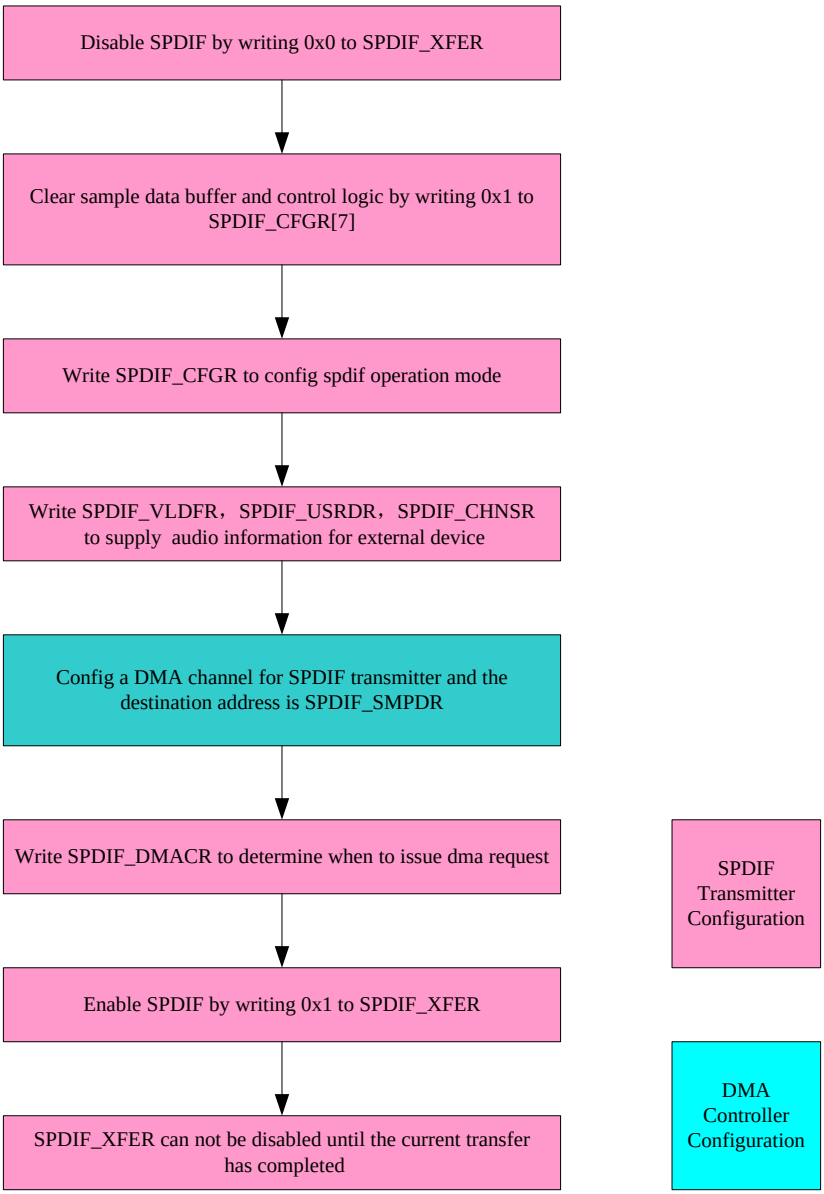

Fig. 23-6 SPDIF transmitter operation flow chart

The above figure shows the operation flow of SPDIF operation. Note that the configuration register can be written only when the transfer is stopped.

# Chapter 24 SPDIF Receiver

## 24.1 Overview

The SPDIF receiver is a self-clocking, serial, unidirectional interface for the interconnection of digital audio equipment for consumer and professional applications, using linear PCM coded audio samples.
It provides the basic structure of the interface. Separate documents define items specific to particular applications.
When used in a professional application, the interface is primarily intended to receive monophonic or stereophonic programmes, at a 48 kHz sampling frequency and with a resolution of up to 24bits per sample; it may alternatively be used to receive signals sampled at 32 kHz or 44.1 kHz.
When used in a consumer application, the interface is primarily intended to receive stereophonic programmes, with a resolution of up to 24 bits per sample.
When used for other purposes, the interface is primarily intended to receive audio data coded other than as linear PCM coded audio samples. Provision is also made to allow the interface to receive data related to computer software or signals coded using non-linear PCM. The format specification for these applications is not part of this standard.
There are 3 SPDIF receivers(SPDIF_RX) in total. That are SPDIF_RX0, SPDIF_RX1 and SPDIF_RX2. Each of them supports following features.

- Support AHB Bus Interface
- Support one internal 30-bit wide and 32-location deep FIFO for receiving audio data
- Support combined interrupt output
- Support DMA handshaking interface and configurable DMA water level
- Support liner PCM(IEC60958) and non-liner PCM(IEC61937)
- Support 16~24 bits audio sample length for liner PCM application
- Support 16 bits audio sample length for non-liner PCM application
- Support up to 384kHz sample rate with the corresponding reference clock equal to 384KHz*64*2*10, that is 491.52MHz
- Support the frequency of reference clock is at least 10 times the frequency of the biphase encoding clock, but not more than 256 times
- Support recovering clock and audio data from input bitstream

## 24.2 Block Diagram

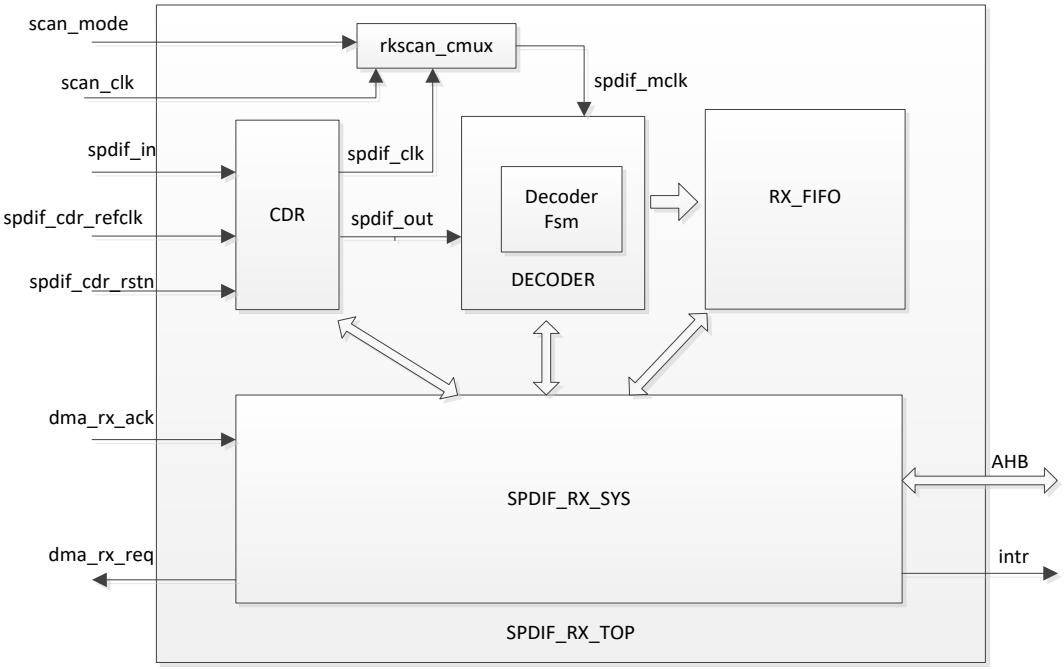

Fig. 24-1 SPDIF receiver Block Diagram

The SPDIF receiver is composed of following modules.

Copyright 2022 © Rockchip Electronics Co., Ltd.

**SPDIF_RX_SYS**
The module implements the AHB slave operation. It contains not only control registers of SPDIF receiver inside but also interrupt and DMA handshaking interface.
**CDR**
The CDR is short for clock and data recovery. Clock and data can be recovered from the input bitstream by using a high frequency reference clock.
**DECODER**
The clock recovered from the CDR is used as the working clock to decode the input bitstream such as extracting audio data, the corresponding preamble code, V/U/C/P flags and other audio information.
**RX_FIFO**
The RX FIFO stores the audio data extracted from input bitstream. The size of the FIFO is 30bitsx32.

# 24.3 Function description

## 24.3.1 Frame Format

SPDIF receiver follows the same protocol(IEC60958/IEC61937) as SPDIF transmitter. A frame is uniquely composed of two sub-frames. For linear coded audio applications, the rate of receiving of frames corresponds exactly to the source sampling frequency.
In the 2-channel operation mode, the samples received from both channels are arranged by time multiplexing in consecutive sub-frames. The first subframe(left channel in stereophonic operation and primary channel in monophonic operation) normally use preamble M. However, the preamble is changed to preamble B once every 192 frame to identify the start of the block structure used to organize the channel status information. The second sub-frame (right in stereophonic operation and secondary channel in monophonic operation) always use preamble W.

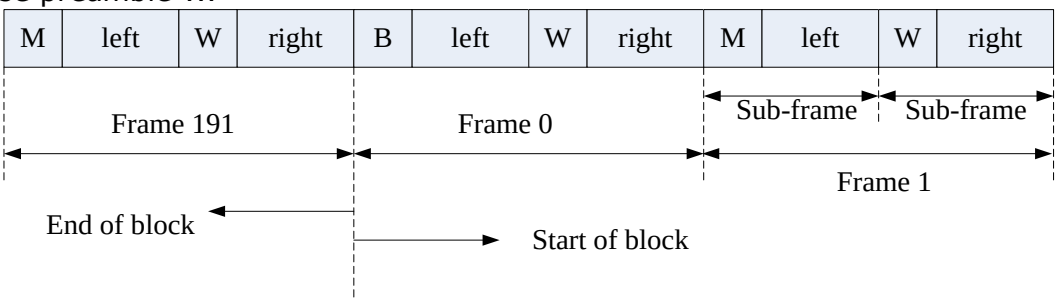

Fig. 24-2 SPDIF Frame Format

In the single channel operation mode in a professional application, the frame format is the same as in the 2-channel mode. Data is carried only in the first sub-frame and may be duplicated in the second sub-frame. If the second sub-frame is not carrying duplicate data, then time slot 28 (validity flag) shall be set to logical '1' (not valid).

## 24.3.2 Sub-frame Format

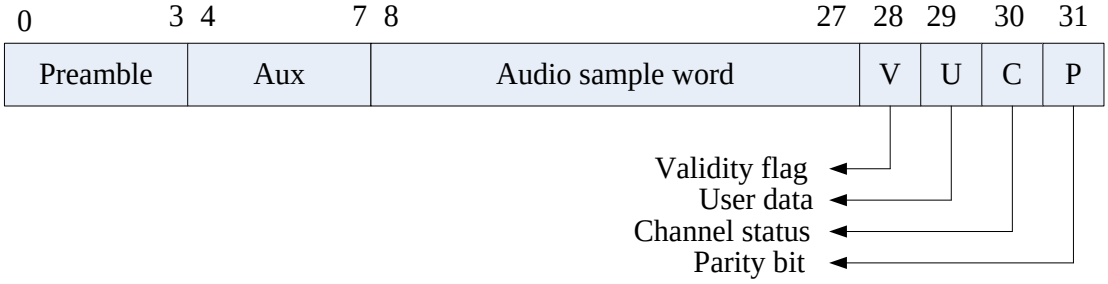

Fig. 24-3 SPDIF Sub-frame Format

Each sub-frame is divided into 32 time slots, numbered from 0 to 31. Time slot 0 to 3 carries one of the three permitted preambles. Time slot 4 to 27 carry the audio sample word in linear 2's complement representation. The MSB is carried by time slot 27. When a 24-bit coding range is used, the LSB is in time slot 4. When a 20-bit coding range is used, time slot 8 to 27 carry the audio sample word with the LSB in time slot 8. Time slot 4 to 7 may be

Copyright 2022 © Rockchip Electronics Co., Ltd. 

used for other application. Under these circumstances, the bits in the time slot 4 to 7 are designated auxiliary sample bits.
If the source provides fewer bits than the interface allows (either 24 or 20), the unused LSBs are set to a logical '0'. For a non-linear PCM audio application or a data application the main data field may carry any other information. Time slot 28 carries the validity flag associated with the main data field. Time slot 29 carries 1 bit of the user data associated with the audio channel transmitted in the same sub-frame. Time slot 30 carries one bit of the channel status words associated with the main data field channel transmitted in the same sub-frame. Time slot 31 carries a parity bit such that time slots 4 to 31 inclusive carries an even number of ones and an even number of zeros.

### 24.3.3 Channel Coding

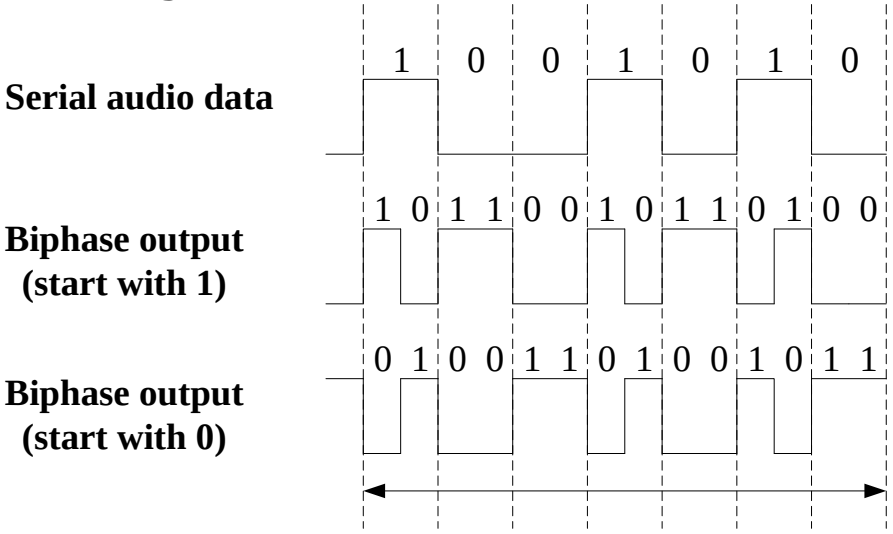

Fig. 24-4 SPDIF Channel Coding

To minimize the direct current component on the transmission/receiving line, to facilitate clock recovery from the data stream and to make the interface insensitive to the polarity of connections, time slots 4 to 31 are encoded in biphase-mark.
Each bit to be transmitted is represented by a symbol comprising two consecutive binary states. The first state of a symbol is always different from the second state of the previous symbol. The second state of the symbol is identical to the first if the bit to be transmitted is logical '0'.However, it is different from the first if the bit is logical '1'.

### 24.3.4 Preamble

Preambles are specific patterns providing synchronization and identification of the sub-frames and blocks.
To achieve synchronization within one sampling period and to make this process completely reliable, these patterns violate the biphase-mark code rules, thereby avoiding the possibility of data imitating the preambles.
A set of three preambles is used. These preambles are transmitted in the time allocated to four time slots (time slots 0 to 3) and are represented by eight successive states. The first state of the preamble is always different from the second state of the previous symbol.

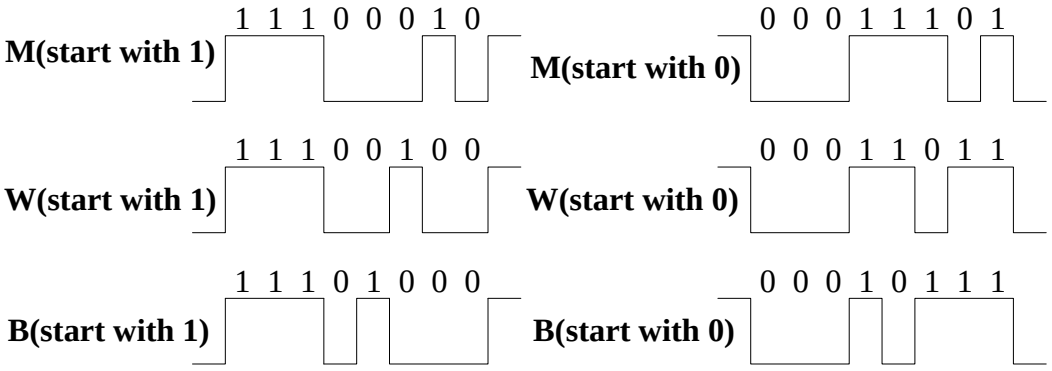

Fig. 24-5 SPDIF Preamble

Like biphase code, these preambles are dc free and provide clock recovery. They differ in at

least two states from any valid biphase sequence.

# 24.4 Register Description

## 24.4.1 Registers Summary

| Name | Offset | Size | Reset Value | Description |
|---|---|---|---|---|
| SPDIF_RX_VERSION | 0x0000 | W | 0x00000100 | Version Register |
| SPDIF_RX_CFGR | 0x0004 | W | 0x00000000 | Transfer Configuration Register |
| SPDIF_RX_CLR | 0x0008 | W | 0x00000000 | Clear Register |

# Chapter 25 Gigabit Media Access Controller (GMAC)

## 25.1 Overview

The Ethernet Quality-of-Service controller(EQOS is commonly referred to as GMAC in this document) provides a complete Ethernet interface from processor to a Reduced Media Independent Interface (RMII) and Reduced Gigabit Media Independent Interface (RGMII) compliant Ethernet PHY. The GMAC includes a DMA controller. The DMA controller efficiently moves packet data from microprocessor's RAM, formats the data for an IEEE 802.3-2002 compliant packet and transmits the data to an Ethernet Physical Interface (PHY). It also efficiently moves packet data from RXFIFO to microprocessor's RAM.
The following features may or may not be present in the actual product. Please contact Rockchip for the actual feature configurations and the third-party licensing requirements.

### 25.1.1 MAC Features

#### 25.1.1.1 MAC Tx and Rx Common Features

- Supports 10/100/1000-Mbps data transfer rates with the RGMII interfaces
- Supports 10/100-Mbps data transfer rates with the RMII interfaces
- Half-duplex operation:
  - CSMA/CD Protocol support
  - Flow control using back-pressure support (based on implementation-specific white papers and UNH Ethernet Clause 4 MAC Test Suite - Annex D)
  - Packet bursting and packet extension in 1000 Mbps half-duplex operation
- Standard IEEE 802.3az-2010 for Energy Efficient Ethernet in Reduced Gigabit Media Independent Interface (RGMII) PHYs
- 64-bit data transfer interface on the application side
- Full-duplex flow control operations (IEEE 802.3x Pause packets and Priority flow control)
- network statistics with RMON or MIB Counters (RFC2819/RFC2665)
- Support Ethernet packet timestamping as described in IEEE 1588-2002 and IEEE 1588-2008 (64-bit timestamps given in the Tx or Rx status of PTP packet). Both one-step and two-step timestamping is supported in TX direction
- Flexibility to control the Pulse-Per-Second (PPS) output signal (ptp_pps_o)
- Media clock generation and recovery
- MDIO (Clause 22 and Clause 45) master interface for PHY device configuration and management

#### 25.1.1.2 MAC Tx Features

- Preamble and start of packet data (SFD) insertion
- Separate 32-bit status for each packet transmitted from the application
- Automatic CRC and pad generation controllable on a per-packet basis
- Programmable packet length to support Standard or Jumbo Ethernet packets with up to 16 KB of size
- Programmable Inter Packet Gap (40–96 bit times in steps of 8)
- IEEE 802.3x Flow Control automatic transmission of zero-quanta Pause packet when flow control input transitions from assertion to de-assertion (in full-duplex mode)
- Source Address field insertion or replacement, and VLAN insertion, replacement, and deletion in transmitted packets with per-packet or static-global control
- Insertion, replacement, or deletion of up to two VLAN tags
- Frame Preemption for MAC Tx

#### 25.1.1.3 MAC Rx Features

- Automatic Pad and CRC Stripping options
- Option to disable Automatic CRC checking
- Preamble and SFD deletion
- Separate 112-bit or 128-bit status
- Programmable watchdog timeout limit
- Flexible address filtering modes:
  - Up to 31 additional 48-bit perfect (DA) address filters with masks for each byte

Copyright 2022 © Rockchip Electronics Co., Ltd.

  - Up to 96 additional 48-bit perfect (DA) address filters that can be selected in blocks of 32 and 64 registers
  - Up to 31 48-bit SA address comparison check with masks for each byte
  - 32 bit, 64 bit, 128 bit, or 256 bit Hash filter (optional) for multicast and unicast (DA) addresses
  - Option to pass all multi-cast addressed packets
  - Promiscuous mode to pass all packets without any filtering for network monitoring
  - Pass all incoming packets (as per filter) with a status report
- Additional packet filtering:
  - VLAN tag-based: Perfect match and Hash-based (optional) filtering. Filtering based on either outer or inner VLAN tag is possible
  - Layer 3 and Layer 4-based: TCP or UDP over IPv4 or IPv6
  - Extended VLAN tag based filtering 4, 8, 16, or 32 filter selection
- IEEE 802.1Q VLAN tag detection and option to delete the VLAN tags in received packets
- Optional module to detect remote wake-up packets and AMD magic packets
- Optional forwarding of received Pause packets to the application (in full-duplex mode)
- Frame Preemption for MAC Rx

## 25.1.2 MTL Features

### 25.1.2.1 MTL Tx and Rx Common Features

- 32-bit, 64-bit, or 128-bit Transaction Layer block (bridges the application and the MAC)
- Data transfers executed using simple FIFO protocol
- Synchronization for all clocks in the design (Transmit, Receive, and Application clocks)
- Optimization for packet-oriented transfers with packets delimiters
- Option to have dual-port RAM based asynchronous FIFO controllers or Single-port RAM based synchronous FIFO controllers
- RAM memory instantiation outside the top-level module to facilitate memory testing or instantiation
- Programmable burst length, up to half the size of the MTL Rx queue or Tx queue size, to support burst data transfer in the EQOS-MTL configuration
- Programmable threshold capability for each queue (default of 64 bytes)
- Optional Debug and slave mode operation on Queue 0 (default queue)

### 25.1.2.2 MTL Tx Features

- TX FIFO sizes on transmission is 16 KB
- Store-and-Forward mechanism or threshold mode (cut-through) for transmission to the MAC
- Programmable queue size in configurations with multiple queues. Each queue size can be programmed in terms of 256 bytes
- Automatic retransmission of collision packets in half-duplex mode
- Discard packets on late collision, excessive collisions, excessive deferral, and under-run conditions with appropriate status
- Disabling of Data Memory RAM chip-select when inactive to reduce power consumption
- Optional module to calculate and insert IPv4 header checksum and TCP, UDP, or ICMP checksum
- Programmable interrupt options for different operational conditions
- Statistics by generating pulses for packets dropped (because of underflow) in the Tx FIFO
- Optional packet-level control for
  - VLAN tag insertion or replacement
  - Ethernet source address insertion
  - Layer3/Layer4 Checksum insertion control
  - One-step timestamp
  - Timestamp control
  - CRC and pad control
- Following scheduling algorithms in configurations with multiple queues:
  - Weighted Round Robin (WRR)
  - (When Data Center Bridging is enabled) Deficit Weighted Round Robin (DWRR)

Copyright 2022 © Rockchip Electronics Co., Ltd.

  - (When Data Center Bridging is enabled) Weighted Fair Queuing (WFQ)
  - Strict Priority (SP)
  - (When Audio-Video Bridging is enabled) Credit-based Shaper (CBS)
  - (When TSN is enabled), Enhancement to Scheduled Traffic (EST)
  - (When TSN is enabled), Time Based Scheduling (TBS)
- Option to support dropping of Tx Status to improve the Transmit throughput

#### 25.1.2.3 MTL Rx Features

- Rx queue sizes in the Receive path is 32 KB
- Insertion of Rx Status vectors into the Rx queue after the EOP transfer (in Threshold mode) and before SOP (in Store-and-Forward mode) in EQOS-MTL configuration
- Programmable Rx queue threshold (default fixed at 64 bytes) in Threshold (or cut-through) mode
- Option to filter all error packets on reception and not forward them to the application in the store-and-forward mode
- Option to forward the undersized good packets
- Statistics by generating pulses for packets dropped (because of overflow) in the Rx FIFO
- Automatic generation of Pause packet control or backpressure signal to the MAC based on the Rx Queue fill level
- Arbitration among queues when multiple queues are present. The following arbitration schemes are supported:
  - Weighted Round Robin (WRR)
  - Weighted Strict priority (WSP)
  - Strict Priority (SP)
- Option to replicate received multicast packets for transfer by multiple Rx DMA channels
- Option to have a programmable lookup table based flexible Parser for filtering and steering the Rx packets

### 25.1.3 DMA Block Features

- 64-bit data transfers
- Separate DMA channel in the Transmit path for each queue in MTL
- Single or multiple DMA channels for any number of queues in MTL Receive path
- Fully synchronous design operating on a single application clock (except for CSR module, when a separate CSR clock is configured)
- Optimization for packet-oriented DMA transfers with packet delimiters
- Byte-aligned addressing for data buffer support
- Dual-buffer (ring) descriptor support
- Descriptor architecture to allow large blocks of data transfer with minimum CPU intervention (each descriptor can transfer up to 32 KB of data)
- Comprehensive status reporting for normal operation and transfers with errors
- Individual programmable burst length for Tx DMA and Rx DMA engines for optimal host bus utilization
- Programmable interrupt options for different operational conditions
- Per-packet Transmit or Receive Complete Interrupt control
- Round-robin or fixed-priority arbitration between the Receive and Transmit engines
- Start and Stop modes
- Separate ports for host CSR access and host data interface
- support for TCP Segmentation Offload (TSO) and UDP Segmentation Offload (USO)
- Selectable number of Tx DMA channels with TSO/USO feature enabled
- Routing of received packets to the DMA channels based on the DA or VLAN Priority in multi-channel DMA configurations
- Option to split the packet header (Layer 3 and Layer 4) and payload in a different buffers
- Time-sensitive conditional packet fetching from system memory by comparing the Slot Time or IEEE 1588 time information provided in the descriptor (useful for AV applications)
- Programmable control for Transmit Descriptor posted writes to improve the throughput
- Sideband signals to control starting and stopping of DMA channels

## 25.2 Block Diagram

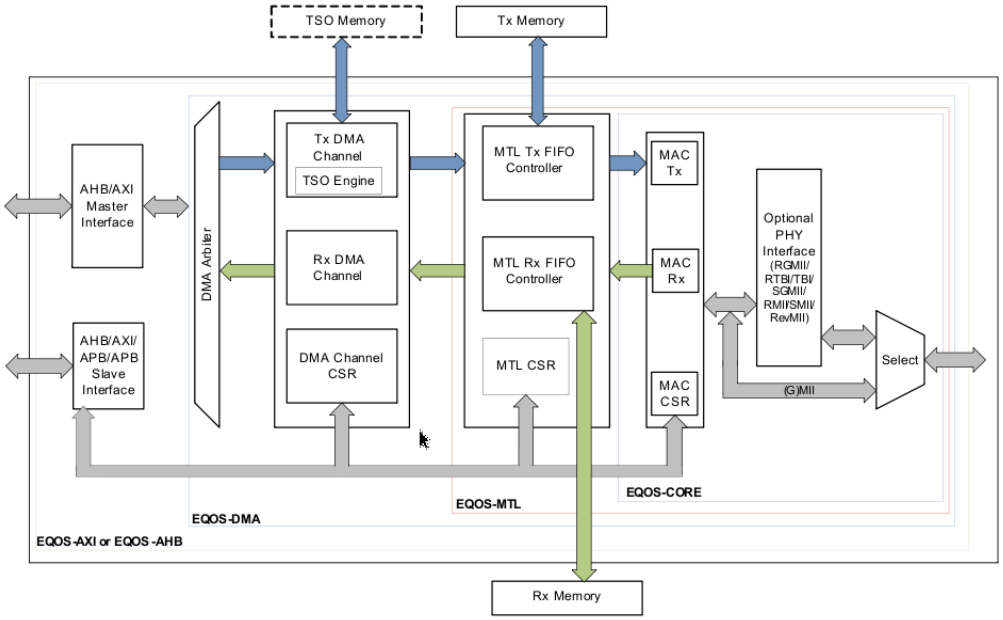

Fig. 25-1 GMAC Block Diagram

The GMAC is broken up into multiple separate functional units. These blocks are interconnected in the MAC module. The block diagram shows the general flow of data and control signals between these blocks.

The GMAC transfers data to system memory through the AXI master interface. The host CPU uses the APB Slave interface to access the GMAC subsystem's control and status registers (CSRs).

The GMAC supports the PHY interfaces of reduced GMII (RGMII) and reduced MII (RMII).

The Transmit FIFO (Tx FIFO) buffers data read from system memory by the DMA before transmission by the GMAC Core. Similarly, the Receive FIFO (Rx FIFO) stores the Ethernet frames received from the line until they are transferred to system memory by the DMA. These are asynchronous FIFOs, as they also transfer the data between the application clock and the GMAC line clocks.

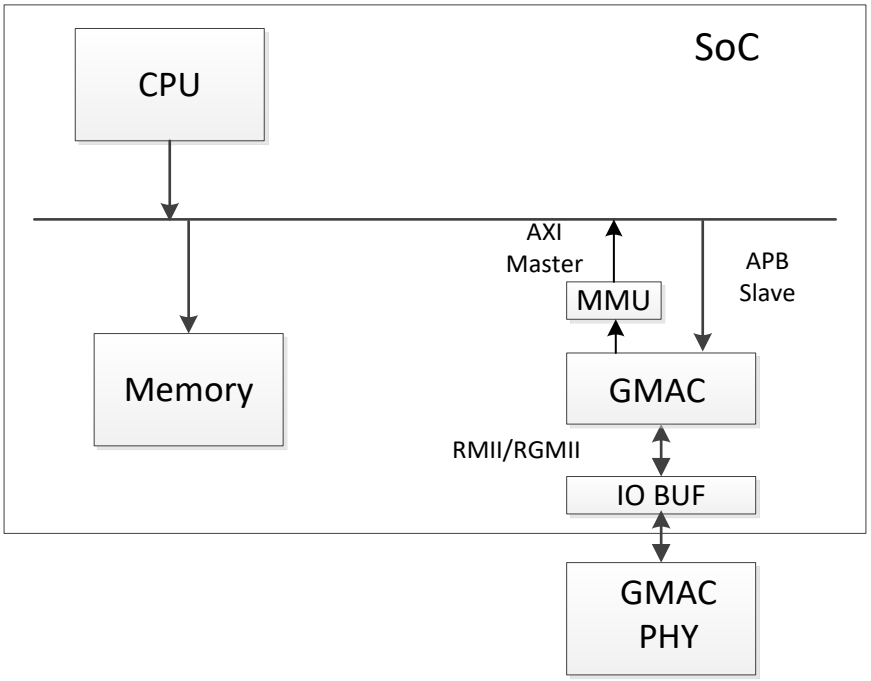

Fig. 25-2 GMAC in SOC

GMAC Supports 10/100/1000-Mbps data transfer rates with the RGMII interfaces and Supports 10/100-Mbps data transfer rates with the RMII interfaces.

# 25.3 Function Description

## 25.3.1 Frame Structure

Data frames transmitted shall have the frame format shown in Fig.1-3.

Fig. 25-3 Frame Format

The preamble <preamble> begins a frame transmission. The bit value of the preamble field consists of 7 octets with the following bit values:
10101010 10101010 10101010 10101010 10101010 10101010 10101010
The SFD (start frame delimiter) <sfd> indicates the start of a frame and follows the preamble. The bit value is 10101011.The data in a well formed frame shall consist of N octet's data.

### 25.3.1.1 RMII Interface timing diagram

The Reduced Media Independent Interface (RMII) specification reduces the pin count between Ethernet PHYs and Switch ASICs (only in 10/100 mode). According to the IEEE 802.3u standard, an MII contains 16 pins for data and control. In devices incorporating multiple MAC or PHY interfaces (such as switches), the number of pins adds significant cost with increase in port count. The RMII specification addresses this problem by reducing the pin count to 7 for each port - a 62.5% decrease in pin count.
The RMII module is instantiated between the GMAC and the PHY. This helps translation of the MAC's MII into the RMII. The RMII block has the following characteristics:
Supports 10-Mbps and 100-Mbps operating rates. It does not support 1000-Mbps operation.
Two clock references are sourced externally or CRU, providing independent, 2-bit wide transmit and receive paths.

### 25.3.1.2 Transmit Bit Ordering

Each nibble from the MII must be transmitted on the RMII a di-bit at a time with the order of di-bit transmission shown in Fig.1-4. The lower order bits (D1 and D0) are transmitted first followed by higher order bits (D2 and D3).

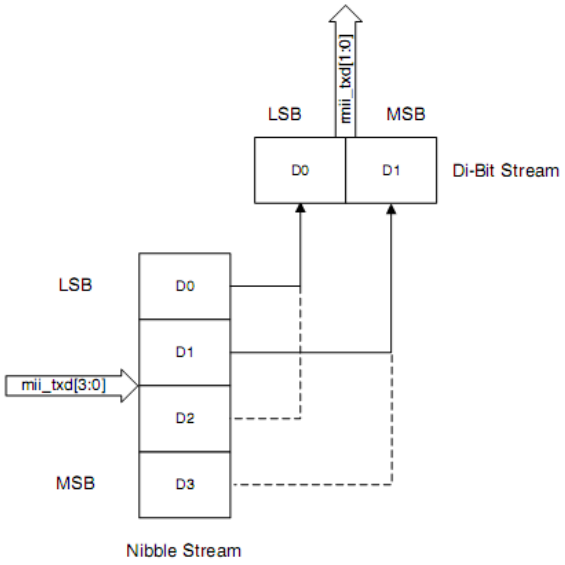

Fig. 25-4 RMII Transmission Bit Ordering

### 25.3.1.3 RMII Transmit Timing Diagrams

Fig.1-5 through 1-8 show MII-to-RMII transaction timing. The clk_rmii_i (REF_CLK) frequency is 50MHz in RMII interface. In 10Mb/s mode, as the REF_CLK frequency is 10 times as the data rate, the value on rmii_txd_o[1:0] (TXD[1:0]) shall be valid such that TXD[1:0] may be sampled every 10th cycle, regard-less of the starting cycle within the group and yield the correct frame data.

Copyright 2022 © Rockchip Electronics Co., Ltd.

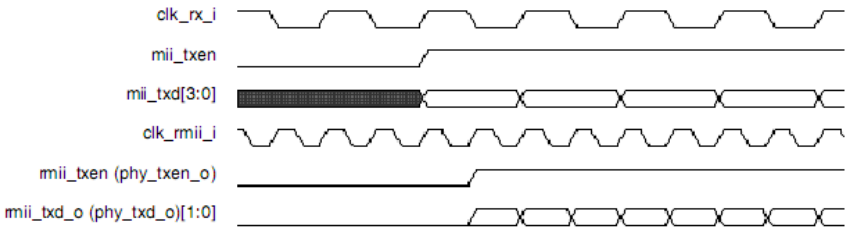

Fig. 25-5 Start of MII and RMII Transmission in 100-Mbps Mode

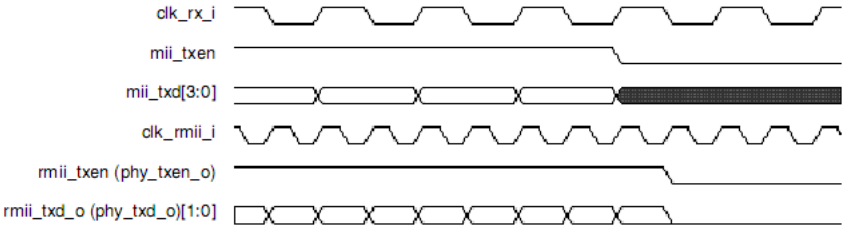

Fig. 25-6 End of MII and RMII Transmission in 100-Mbps Mode

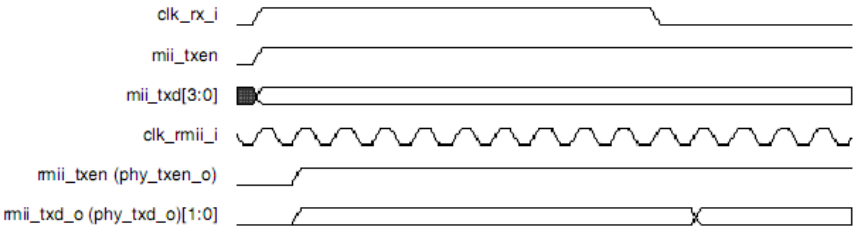

Fig. 25-7 Start of MII and RMII Transmission in 10-Mbps Mode

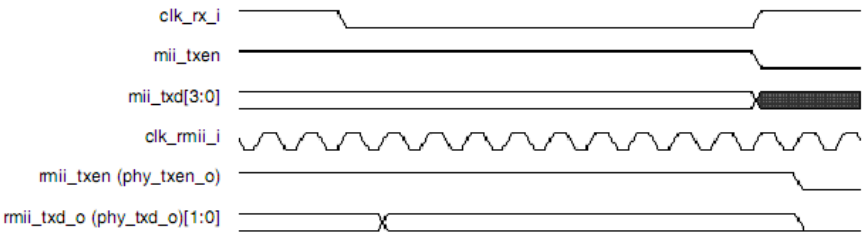

Fig. 25-8 End of MII and RMII Transmission in 10-Mbps Mode

#### 25.3.1.4 Receive Bit Ordering

Each nibble is transmitted to the MII from the di-bit received from the RMII in the nibble transmission order shown in Fig.1-9. The lower order bits (D0 and D1) are received first, followed by the higher order bits (D2 and D3).

Copyright 2022 © Rockchip Electronics Co., Ltd.

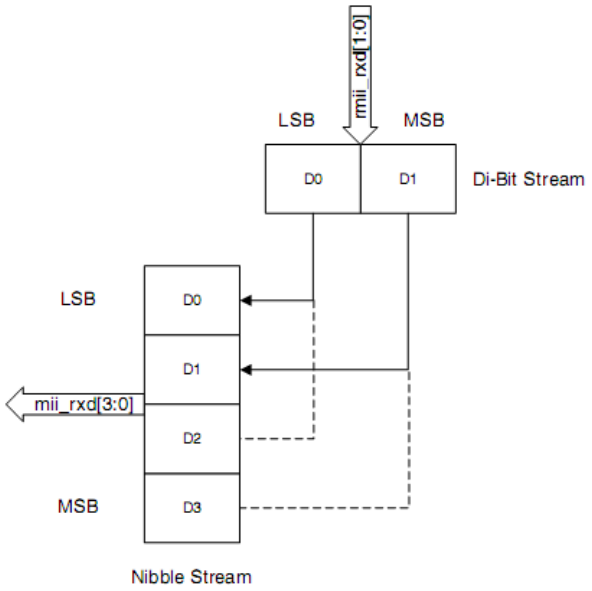

Fig. 25-9 RMII Receive Bit Ordering

#### 25.3.1.5 RGMII Interface

The Reduced Gigabit Media Independent Interface (RGMII) specification reduces the pin count of the interconnection between the GMAC 10/100/1000 controller and the PHY for GMII and MII interfaces. To achieve this, the data path and control signals are reduced and multiplexed together with both the edges of the transmission and receive clocks. For gigabit operation the clocks operate at 125 MHz; for 10/100 operation, the clock rates are 2.5 MHz/25 MHz.

In the GMAC 10/100/1000 controller, the RGMII module is instantiated between the GMAC core's GMII and the PHY to translate the control and data signals between the GMII and RGMII protocols.

The RGMII block has the following characteristics:

- Supports 10-Mbps, 100-Mbps, and 1000-Mbps operation rates
- For the RGMII block, no extra clock is required because both the edges of the incoming clocks are used
- The RGMII block extracts the in-band (link speed, duplex mode and link status) status signals from the PHY and provides them to the GMAC core logic for link detection

### 25.3.2 Station Management Agent

The application can access the PHY registers through the Station Management Agent (SMA) module. SMA is a two-wire Station Management interface (MIM).

For MIM accesses, the maximum operating frequency of the MDC (gmii_mdc_o) is 2.5 MHz, as specified in the IEEE 802.3. In the GMAC core, the gmii_mdc_o clock is derived from the application clock or clk_csr_i, using a divider-counter. The divide factor depends on the clock range setting (CR field) in the MAC_MDIO_Address register Select the clock divide factor as mentioned in the description of CR field of MAC_MDIO_Address register, to meet IEEE specifications. However, if your system supports higher clock frequencies on the MIM interface, there is a provision to select a different divider.

The MDIO frame structure is as follows:

Table 25-1 MDIO Clause 45 Frame Structure

| Field | Description |
|---|---|
| IDLE | The mdio line is in tri-state; there is no clock on gmii_mdc_o signal. |
| PREAMBLE | 32 continuous bits of value 1 |
| START | Start of packet is 2'b00 |
| OPCODE | ■ 2'b00<br>■ 2'b01<br>■ 2'b10 |

Copyright 2022 © Rockchip Electronics Co., Ltd.

| Field | Description |
|---|---|
| | ■ 2'b11 |
| PHY ADDR | 5-bit address select for one of 32 PHYs |
| DEV ADDR | 5-bit address select for one of 32 devices |
| TA | Turnaround<br>■ 2'bZ0: Read and post-read increment address<br>■ 2'b10: Write and address MDIO accesses<br>Where Z is the tri-state level |
| DATA/ADDRESS | 16-bit value: For an address cycle (OPCODE = 2'b00), this frame contains the address of the register to be accessed on the next cycle. For the data cycle of a write frame, this field contains the data to be written to the register. For read or post-read increment address frames, this field contains the contents of the register read from the PHY.<br>■ In address and data write cycles, the GMAC drives the MDIO line during the transfer of these 16 bits.<br>■ In read and post-read increment address cycles, the PHY drives the MDIO line during the transfer of these 16 bits. |

The frame structure for Clause 22 frames is also supported. The C45E bit in the MAC_MDIO_Address register can be programmed to enable Clause 22 or Clause 45 mode of operation. Table.1-2 shows the Clause 22 frame format.

Table 25-2 MDIO Clause 22 Frame Structure

| Field | Description |
|---|---|
| IDLE | The mdio line is in tri-state; there is no clock on gmii_mdc_o signal. |
| PREAMBLE | 32 continuous bits of value 1 |
| START | Start of packet is 2'b01 |
| OPCODE | ■ 2'b01 : Write<br>■ 2'b10 : Read |
| PHY ADDR | 5-bit address select for one of 32 PHYs |
| DEV ADDR | 5-bit address to select the register within each MMD |
| TA | Turnaround<br>■ 2'bZ0: Read and post-read increment address<br>■ 2'b10: Write and address MDIO accesses<br>Where Z is the tri-state level |
| DATA/ADDRESS | Any 16-bit value:<br>■ In a write operation, the GMAC drives MDIO<br>■ In read operation, the PHY drives MDIO |

In addition to normal read and write operations, the SMA also supports post-read increment address while operating in Clause 45 mode.

### 25.3.3 Power Management and Energy Efficient Ethernet

The GMAC supports the following techniques to save power.

- Magic Packet
- Remote Wakeup
- Energy Efficient Ethernet

The Magic Packet and Remove Wakeup techniques are used to save power in the host

system when it is idle (Sleep mode) and has to be woken up only at the reception of specific packets from the Ethernet network. In the Sleep mode, the power to the host logic along with majority of the GMAC (except the MAC receiver logic), can be shut down. On receiving the specific packets from the network, the MAC provides the trigger to restore the power to the host system and come back to normal state.
The Energy Efficient Ethernet (EEE) mode is compliant with the IEEE 802.3az-2010 standard. It is primarily targeted to save power in the Ethernet port when there is no traffic on the line. In this mode, the host indicates to the far-end that it does not have any packets to transmit for near future and puts the transmitter port (MAC Controller, PCS and PHY layers) into low-power mode. Similarly, the Receiver port can also be put into low-power mode when the far-end host indicates that it does not have any traffic to transfer. This allows significant saving of power in the Ethernet port (mainly in the PHY) with intermittent and bursty traffic profile. The triggering of entry and exit out of the EEE mode is controlled by the MAC and is supported within the GMAC.
Simultaneous operation of the EEE mode along with any or both the other power saving modes is also supported in GMAC.

### 25.3.4 IEEE 1588 Timestamp Support

The IEEE 1588 defines a Precision Time Protocol (PTP) which enables precise synchronization of time in measurement and control systems. This protocol enables heterogeneous systems that include clocks of varying inherent precision, resolution, and stability to synchronize. The protocol supports system-wide synchronization accuracy in the sub-microsecond range with minimal network and local clock computing resources.
The GMAC supports the IEEE 1588-2002 (version 1) and IEEE 1588-2008 (version 2). The IEEE 1588-2002 supports PTP transported over UDP/IP and IEEE 1588-2008 supports PTP transported over Ethernet. The GMAC provides programmable support for both standards. The controller supports the following features:

- Provides an option to take snapshot of all packets or only PTP type packets
- Provides an option to take snapshot of only event messages
- Provides an option to take the snapshot based on the clock type: ordinary, boundary, end-to-end transparent, and peer-to-peer transparent
- Provides an option to select the node to be a master or slave for ordinary and boundary clock
- Identifies the PTP message type, version, and PTP payload in packets sent directly over Ethernet and sends the status
- Provides an option to measure sub-second time in digital or binary format

### 25.3.5 TCP/IP Segmentation Offload (TSO) Engine

The TCP Segmentation Offload (TSO) engine is useful in offloading the TCP segmentation functions to the hardware.
It also supports UDP Segmentation Offload (USO) in which the UDP payload is segmented in the hardware. There are no sequencing/ordering controls available or updated in the segments, so it can be used in point to point applications in which out of order packets are not expected by the receiver. The description and flow of TSO mentioned in this section is same as USO, any deviation is provided as notes.
In the TCP segmentation offload (TSO) feature, the DMA splits a large TCP packet into multiple small packets and passes these packets to the MTL Tx Queue.

### 25.3.6 MAC Management Counters

The GMAC supports storing the statistics about the received and transmitted packets in registers that are accessible through the application.
The counters in the MAC Management Counters (MMC) module can be viewed as an extension of the register address space of the CSR module. The MMC module maintains a set of registers for gathering statistics on the received and transmitted packets. The register set includes a control register for controlling the behavior of the registers, two status registers containing interrupts generated (receive and transmit), and Interrupt Enable registers (receive and transmit). These registers are accessible from the Application through

Copyright 2022 © Rockchip Electronics Co., Ltd. 

the MAC Control Interface (MCI). Each register is 32-bits wide. The write data is qualified with the corresponding mci_be_i signals. Therefore, non-32-bit accesses are allowed as long as the address is word-aligned. The MMCs are accessed using transactions, in the same way the CSR address space is accessed.
The MMC counters are free running. There is no separate enable for the counters to start. If a particular MMC counter is present in the RTL, it starts counting when corresponding packet is received or transmitted. The Receive MMC counters are updated for packets that are passed by the Address Filter (AFM) block. The statistics of packets, dropped by the AFM module, are not updated unless they are runt packets of less than 6 bytes (DA bytes are not received fully). To get statistics of all packets, set Bit 0 in the “MAC_Packet_Filter” register.
The MMC module gathers statistics on encapsulated IPv4, IPv6, TCP, UDP, or ICMP payloads in received Ethernet packets.

# 25.4 Register Description

## 25.4.1 Registers Summary

| Name | Offset | Size | Reset Value | Description |
|---|---|---|---|---|
| GMAC_MAC_Configuration | 0x0000 | W | 0x00000000 | The MAC Configuration Register establishes the operating mode of the MAC |
| GMAC_MAC_Ext_Configuration | 0x0004 | W | 0x00000000 | The MAC Extended Configuration Register establishes the operating mode of the MAC |
| GMAC_MAC_Packet_Filter | 0x0008 | W | 0x00000000 | The MAC Packet Filter register contains the filter controls for receiving packets |
| GMAC_MAC_Watchdog_Timeout | 0x000c | W | 0x00000000 | The Watchdog Timeout register controls the watchdog timeout for received packets |
| GMAC_MAC_Hash_Table_Reg0 | 0x0010 | W | 0x00000000 | The Hash Table Register 0 contains the first 32 bits of the hash table |
| GMAC_MAC_Hash_Table_Reg1 | 0x0014 | W | 0x00000000 | The Hash Table Register 1 contains the second 32 bits of the hash table |
| GMAC_MAC_Hash_Table_Reg2 | 0x0018 | W | 0x00000000 | The Hash Table Register 2 contains the third 32 bits of the hash table |
| GMAC_MAC_VLAN_Tag_Ctrl | 0x0050 | W | 0x00000000 | This register is the redefined format of the MAC VLAN Tag Register. It is used for indirect addressing. It contains the address offset, command type and Busy Bit for CSR access of the Per VLAN Tag registers |

Copyright 2022 © Rockchip Electronics Co., Ltd.

| Name | Offset | Size | Reset Value | Description |
|---|---|---|---|---|
| GMAC_MAC_VLAN_Tag_Data | 0x0054 | W | 0x00000000 | This register holds the read/write data for Indirect Access of the Per VLAN Tag registers.During the read access, this field contains valid read data only after the OB bit is reset. During the write access, this field should be valid prior to setting the OB bit in the MAC_VLAN_Tag_Ctrl Register |
| GMAC_MAC_VLAN_Hash_Table | 0x0058 | W | 0x00000000 | When VTHM bit of the MAC_VLAN_Tag register is set, the 16-bit VLAN Hash Table register is used for group address filtering based on the VLAN tag |
| GMAC_MAC_VLAN_Incl | 0x0060 | W | 0x00000000 | The VLAN Tag Inclusion or Replacement register contains the VLAN tag for insertion or replacement in the Transmit packets. It also contains the VLAN tag insertion controls |
| GMAC_MAC_Inner_VLAN_Incl | 0x0064 | W | 0x00000000 | The Inner VLAN Tag Inclusion or Replacement register contains the inner VLAN tag to be inserted or replaced in the Transmit packet. It also contains the inner VLAN tag insertion controls |
| GMAC_MAC_Q0_Tx_Flow_Ctrl | 0x0070 | W | 0x00000000 | The Flow Control register controls the generation and reception of the Control (Pause Command) packets by the Flow control module of the MAC |
| GMAC_MAC_Rx_Flow_Ctrl | 0x0090 | W | 0x00000000 | The Receive Flow Control register controls the pausing of MAC Transmit based on the received Pause packet |
| GMAC_MAC_RxQ_Ctrl4 | 0x0094 | W | 0x00000000 | The Receive Queue Control 4 register controls the routing of unicast and multicast packets that fail the Destination or Source address filter to the Rx queues |
| GMAC_MAC_RxQ_Ctrl0 | 0x00a0 | W | 0x00000000 | The Receive Queue Control 0 register controls the queue management in the MAC Receiver |
| GMAC_MAC_RxQ_Ctrl1 | 0x00a4 | W | 0x00000000 | The Receive Queue Control 1 register controls the routing of multicast, broadcast, AV, DCB, and untagged packets to the Rx queues |

Copyright 2022 © Rockchip Electronics Co., Ltd.

| Name | Offset | Size | Reset Value | Description |
|---|---|---|---|---|
| GMAC_MAC_RxQ_Ctrl2 | 0x00a8 | W | 0x00000000 | This register controls the routing of tagged packets based on the USP (user Priority) field of the received packets to the RxQueues 0 to 3 |
| GMAC_MAC_Interrupt_Status | 0x00b0 | W | 0x00000000 | The Interrupt Status register contains the status of interrupts |
| GMAC_MAC_Interrupt_Enable | 0x00b4 | W | 0x00000000 | The Interrupt Enable register contains the masks for generating the interrupts |
| GMAC_MAC_Rx_Tx_Status | 0x00b8 | W | 0x00000000 | The Receive Transmit Status register contains the Receive and Transmit Error status |
| GMAC_MAC_PMT_Control_Status | 0x00c0 | W | 0x00000000 | The PMT Control and Status Register |
| GMAC_MAC_RWK_Packet_Filter | 0x00c4 | W | 0x00000000 | The Remote Wakeup Filter registers are implemented as 8, 16, or 32 indirect access registers (wkuppktfilter_reg#i) based on whether 4, 8, or 16 Remote Wakeup Filters are selected in the configuration and accessed by application through MAC_RWK_Packet_Filter register |
| GMAC_RWK_Filter0_Byte_Mask | 0x00c4 | W | 0x00000000 | RWK Filter0 Byte Mask |
| GMAC_RWK_Filter1_Byte_Mask | 0x00c4 | W | 0x00000000 | RWK Filter1 Byte Mask |
| GMAC_RWK_Filter2_Byte_Mask | 0x00c4 | W | 0x00000000 | RWK Filter2 Byte Mask |
| GMAC_RWK_Filter3_Byte_Mask | 0x00c4 | W | 0x00000000 | RWK Filter3 Byte Mask |
| GMAC_RWK_Filter01_CRC | 0x00c4 | W | 0x00000000 | RWK Filter 0/1 CRC-16 |
| GMAC_RWK_Filter23_CRC | 0x00c4 | W | 0x00000000 | RWK Filter 2/3 CRC-16 |
| GMAC_RWK_Filter_Offset | 0x00c4 | W | 0x00000000 | RWK Filter Offset |
| GMAC_RWK_Filter_Command | 0x00c4 | W | 0x00000000 | RWK Filter Command |
| GMAC_MAC_LPI_Control_Status | 0x00d0 | W | 0x00000000 | The LPI Control and Status Register controls the LPI functions and provides the LPI interrupt status. The status bits are cleared when this register is read |
| GMAC_MAC_LPI_Timers_Control | 0x00d4 | W | 0x03e80000 | The LPI Timers Control register controls the timeout values in the LPI states. |
| GMAC_MAC_LPI_Entry_Timer | 0x00d8 | W | 0x00000000 | This register controls the Tx LPI entry timer |
| GMAC_MAC_1US_Tic_Counter | 0x00dc | W | 0x0000003f | This register controls the generation of the Reference time (1 microsecond tic) |

| Name | Offset | Size | Reset Value | Description |
|---|---|---|---|---|
| GMAC_MAC_PHYIF_Control_Status | 0x00f8 | W | 0x00000000 | PHY Interface Control and Status Register |
| GMAC_MAC_Version | 0x0110 | W | 0x00003051 | The version register identifies the version of the GMAC |
| GMAC_MAC_Debug | 0x0114 | W | 0x00000000 | The Debug register provides the debug status of various MAC blocks |
| GMAC_MAC_HW_Feature0 | 0x011c | W | 0x181173f3 | This register indicates the presence of first set of the optional features or functions |
| GMAC_MAC_HW_Feature1 | 0x0120 | W | 0x111e01e8 | This register indicates the presence of second set of the optional features or functions |
| GMAC_MAC_HW_Feature2 | 0x0124 | W | 0x11041041 | This register indicates the presence of third set of the optional features or functions |
| GMAC_MAC_HW_Feature3 | 0x0128 | W | 0x0c370031 | This register indicates the presence of fourth set the optional features or functions |
| GMAC_MAC_MDIO_Address | 0x0200 | W | 0x00000000 | The MDIO Address register controls the management cycles to external PHY through a management interface |
| GMAC_MAC_MDIO_Data | 0x0204 | W | 0x00000000 | The MDIO Data register stores the Write data to be written to the PHY register located at the address specified in MAC_MDIO_Address |
| GMAC_MAC_ARP_Address | 0x0210 | W | 0x00000000 | The ARP Address register contains the IPv4 Destination Address of the MAC |
| GMAC_MAC_CSR_SW_Ctrl | 0x0230 | W | 0x00000000 | This register contains SW programmable controls for changing the CSR access response and status bits clearing |
| GMAC_MAC_FPE_CTRL_STS | 0x0234 | W | 0x00000000 | This register controls the operation of Frame Preemption |
| GMAC_MAC_Ext_Cfg1 | 0x0238 | W | 0x00000000 | This register contains Split mode control field and offset field for Split Header feature |
| GMAC_MAC_Presn_Time_ns | 0x0240 | W | 0x00000000 | This register contains the 32-bit binary rollover equivalent time of the PTP System Time in ns |

*Copyright 2022 © Rockchip Electronics Co., Ltd.*

| Name | Offset | Size | Reset Value | Description |
|---|---|---|---|---|
| GMAC_MAC_Presn_Time_Updt | 0x0244 | W | 0x00000000 | This field holds the 32-bit value of MAC 1722 Presentation Time in ns, that should be added to the Current Presentation Time Counter value. Init happens when TSINIT is set, and update happens when the TSUPDT bit is set (TSINIT and TSINIT defined in MAC_Timestamp_ Control register |
| GMAC_MAC_Address0_High | 0x0300 | W | 0x0000ffff | The MAC Address0 High register holds the upper 16 bits of the first 6-byte MAC address of the station |
| GMAC_MAC_Address0_Low | 0x0304 | W | 0xffffffff | The MAC Address0 Low register holds the lower 32 bits of the 6-byte first MAC address of the station |
| GMAC_MMC_Control | 0x0700 | W | 0x00000000 | This register establishes the operating mode of MMC |
| GMAC_MMC_Rx_Interrupt | 0x0704 | W | 0x00000000 | Maintains the interrupts generated from all Receive statistics counters |
| GMAC_MMC_Tx_Interrupt | 0x0708 | W | 0x00000000 | Maintains the interrupts generated from all Transmit statistics counters |
| GMAC_MMC_Rx_Interrupt_Mask | 0x070c | W | 0x00000000 | This register maintains the masks for interrupts generated from all Receive statistics counters |
| GMAC_MMC_Tx_Interrupt_Mask | 0x0710 | W | 0x00000000 | This register maintains the masks for interrupts generated from all Transmit statistics counters |
| GMAC_Tx_Octet_Count_Good_Bad | 0x0714 | W | 0x00000000 | This register provides the number of bytes transmitted by the GMAC, exclusive of preamble and retried bytes, in good and bad packets |
| GMAC_Tx_Packet_Count_Good_Bad | 0x0718 | W | 0x00000000 | This register provides the number of good and bad packets, exclusive of retried packets |
| GMAC_Tx_Underflow_Error_Packets | 0x0748 | W | 0x00000000 | This register provides the number of packets aborted because of packets underflow error |
| GMAC_Tx_Carrier_Error_Packets | 0x0760 | W | 0x00000000 | This register provides the number of packets aborted because of carrier sense error (no carrier or loss of carrier) |

Copyright 2022 © Rockchip Electronics Co., Ltd.

| Name | Offset | Size | Reset Value | Description |
|---|---|---|---|---|
| GMAC_Tx_Octet_Count_Good | 0x0764 | W | 0x00000000 | This register provides the number of bytes exclusive of preamble, only in good packets |
| GMAC_Tx_Packet_Count_Good | 0x0768 | W | 0x00000000 | This register provides the number of good packets transmitted by GMAC |
| GMAC_Tx_Pause_Packets | 0x0770 | W | 0x00000000 | This register provides the number of good Pause packets transmitted by GMAC |
| GMAC_Rx_Packets_Count_Good_Bad | 0x0780 | W | 0x00000000 | This register provides the number of good and bad packets received by GMAC |
| GMAC_Rx_Octet_Count_Good_Bad | 0x0784 | W | 0x00000000 | This register provides the number of bytes received by GMAC, exclusive of preamble, in good and bad packets |
| GMAC_Rx_Octet_Count_Good | 0x0788 | W | 0x00000000 | This register provides the number of bytes received by GMAC, exclusive of preamble, only in good packets |
| GMAC_Rx_Multicast_Packets_Good | 0x0790 | W | 0x00000000 | This register provides the number of good multicast packets received by GMAC |
| GMAC_Rx_CRC_Error_Packets | 0x0794 | W | 0x00000000 | This register provides the number of packets received by GMAC with CRC error |
| GMAC_Rx_Oversize_Packets_Good | 0x07a8 | W | 0x00000000 | This register provides the number of packets received by GMAC without errors, with length greater than the maxsize (1,518 bytes or 1,522 bytes for VLAN tagged packets; 2000 bytes if enabled in the S2KP bit of the MAC_Configuration register) |
| GMAC_Rx_Length_Error_Packets | 0x07c8 | W | 0x00000000 | This register provides the number of packets received by GMAC with length error (Length Type field not equal to packet size), for all packets with valid length field |
| GMAC_Rx_Pause_Packets | 0x07d0 | W | 0x00000000 | This register provides the number of good and valid Pause packets received by GMAC |
| GMAC_Rx_FIFO_Overflow_Packets | 0x07d4 | W | 0x00000000 | This register provides the number of missed received packets because of FIFO overflow |

| GMAC_MMC_Rx_FPE_Fragment_Cntr | 0x08d4 | W | 0x00000000 | This register provides the number of additional mPackets transmitted due to preemption |
| GMAC_MAC_L3_L4_Control0 | 0x0900 | W | 0x00000000 | The Layer 3 and Layer 4 Control register controls the operations of filter 0 of Layer 3 and Layer 4 |
| GMAC_MAC_Layer4_Address0 | 0x0904 | W | 0x00000000 | The MAC_Layer4_Address0, MAC_L3_L4_Control0, MAC_Layer3_Addr0_Reg0, MAC_Layer3_Addr1_Reg0, MAC_Layer3_Addr2_Reg0 and MAC_Layer3_Ad dr3_Reg0 registers are reserved (RO with default value) if Enable Layer 3 and Layer 4 Packet Filter option is not selected while configuring the core |
| GMAC_MAC_Layer3_Addr0_Reg0 | 0x0910 | W | 0x00000000 | For IPv4 packets, the Layer 3 Address 0 Register 0 register contains the 32-bit IP Source Address field. For IPv6 packets, it contains Bits[31:0] of the 128-bit IP Source Address or Destination Address field |
| GMAC_MAC_Layer3_Addr1_Reg0 | 0x0914 | W | 0x00000000 | For IPv4 packets, the Layer 3 Address 1 Register 0 register contains the 32-bit IP Destination Address field. For IPv6 packets, it contains Bits[63:32] of the 128-bit IP Source Address or Destination Address field |
| GMAC_MAC_Layer3_Addr2_Reg0 | 0x0918 | W | 0x00000000 | The Layer 3 Address 2 Register 0 register is reserved for IPv4 packets. For IPv6 packets, it contains Bits[95:64] of 128-bit IP Source Address or Destination Address field |
| GMAC_MAC_Layer3_Addr3_Reg0 | 0x091c | W | 0x00000000 | The Layer 3 Address 3 Register 0 register is reserved for IPv4 packets. For IPv6 packets, it contains Bits[127:96] of 128-bit IP Source Address or Destination Address field |
| GMAC_MAC_Timestamp_Control | 0x0b00 | W | 0x00000000 | This register controls the operation of the System Time generator and processing of PTP packets for timestamping in the Receiver |

Copyright 2022 © Rockchip Electronics Co., Ltd.

| Name | Offset | Size | Reset Value | Description |
|---|---|---|---|---|
| GMAC_MAC_Sub_Second_Increment | 0x0b04 | W | 0x00000000 | Specifies the value to be added to the internal system time register every cycle of clk_ptp_ref_i clock |
| GMAC_MAC_System_Time_Secs | 0x0b08 | W | 0x00000000 | The System Time Nanoseconds register, along with System Time Seconds register, indicates the current value of the system time maintained by the MAC |
| GMAC_MAC_System_Time_NS | 0x0b0c | W | 0x00000000 | The System Time Nanoseconds register, along with System Time Seconds register, indicates the current value of the system time maintained by the MAC |
| GMAC_MAC_Sys_Time_Secs_Update | 0x0b10 | W | 0x00000000 | The System Time Seconds Update register, along with the System Time Nanoseconds Update register, initializes or updates the system time maintained by the MAC |
| GMAC_MAC_Sys_Time_NS_Update | 0x0b14 | W | 0x00000000 | MAC System Time Nanoseconds Update register |
| GMAC_MAC_Timestamp_Addend | 0x0b18 | W | 0x00000000 | Timestamp Addend register. This register value is used only when the system time is configured for Fine Update mode (TSCFUPDT bit in the MAC_Timestamp_Control register) |
| GMAC_MAC_Timestamp_Status | 0x0b20 | W | 0x00000000 | Timestamp Status register. All bits except Bits[27:25] gets cleared when the application reads this register |
| GMAC_MAC_Tx_TS_Status_NS | 0x0b30 | W | 0x00000000 | This register contains the nanosecond part of timestamp captured for Transmit packets when Tx status is disabled |
| GMAC_MAC_Tx_TS_Status_Secs | 0x0b34 | W | 0x00000000 | The register contains the higher 32 bits of the timestamp (in seconds) captured when a PTP packet is transmitted |
| GMAC_MAC_Auxiliary_Control | 0x0b40 | W | 0x00000000 | The Auxiliary Timestamp Control register controls the Auxiliary Timestamp snapshot |
| GMAC_MAC_Auxiliary_TS_NS | 0x0b48 | W | 0x00000000 | The Auxiliary Timestamp Nanoseconds register, along with MAC_Auxiliary_Timestamp_Seconds, gives the 64-bit timestamp stored as auxiliary snapshot |

Copyright 2022 © Rockchip Electronics Co., Ltd.

| Name | Offset | Size | Reset Value | Description |
|---|---|---|---|---|
| GMAC_MAC_Auxiliary_TS_Secs | 0x0b4c | W | 0x00000000 | The Auxiliary Timestamp - Seconds register contains the lower 32 bits of the Seconds field of the auxiliary timestamp register |
| GMAC_MAC_TS_Ingress_Corr_NS | 0x0b58 | W | 0x00000000 | This register contains the correction value in nanoseconds to be used with the captured timestamp value in the ingress path |
| GMAC_MAC_TS_Egress_Corr_NS | 0x0b5c | W | 0x00000000 | This register contains the correction value in nanoseconds to be used with the captured timestamp value in the egress path |
| GMAC_MAC_TS_Ingress_Latency | 0x0b68 | W | 0x00000000 | This register holds the Ingress MAC latency |
| GMAC_MAC_TS_Egress_Latency | 0x0b6c | W | 0x00000000 | This register holds the Egress MAC latency |
| GMAC_MAC_PPS_Control | 0x0b70 | W | 0x00000000 | PPS Control register |
| GMAC_MAC_PPS0_Target_Time_Seconds | 0x0b80 | W | 0x00000000 | The PPS Target Time Seconds register, along with PPS Target Time Nanoseconds register, is used to schedule an interrupt event [Bit 1 of MAC_Timestamp_Status] when the system time exceeds the value programmed in these registers |
| GMAC_MAC_PPS0_Target_Time_Ns | 0x0b84 | W | 0x00000000 | PPS0 Target Time Nanoseconds register |
| GMAC_MAC_PPS0_Interval | 0x0b88 | W | 0x00000000 | The PPS0 Interval register contains the number of units of sub-second increment value between the rising edges of PPS0 signal output (ptp_pps_o[0]) |
| GMAC_MAC_PPS0_Width | 0x0b8c | W | 0x00000000 | The PPS0 Width register contains the number of units of sub-second increment value |
| GMAC_MTL_Operation_Mode | 0x0c00 | W | 0x00000000 | The Operation Mode register establishes the Transmit and Receive operating modes and commands |
| GMAC_MTL_DBG_CTL | 0x0c08 | W | 0x00000000 | The FIFO Debug Access Control and Status register controls the operation mode of FIFO debug access |
| GMAC_MTL_DBG_STS | 0x0c0c | W | 0x01900000 | The FIFO Debug Status register contains the status of FIFO debug access |
| GMAC_MTL_FIFO_Debug_Data | 0x0c10 | W | 0x00000000 | The FIFO Debug Data register contains the data to be written to or read from the FIFOs |

Copyright 2022 © Rockchip Electronics Co., Ltd.

| Name | Offset | Size | Reset Value | Description |
|---|---|---|---|---|
| GMAC_MTL_Interrupt_Status | 0x0c20 | W | 0x00000000 | The software driver (application) reads this register during interrupt service routine or polling to determine the interrupt status of MTL queues and the MAC |
| GMAC_MTL_RxQ_DMA_Map0 | 0x0c30 | W | 0x00000000 | The Receive Queue and DMA Channel Mapping 0 register is reserved in EQOS-CORE and EQOS-MTL configurations |
| GMAC_MTL_TBS_CTRL | 0x0c40 | W | 0x00000000 | This register controls the operation of Time Based Scheduling |
| GMAC_MTL_EST_Control | 0x0c50 | W | 0x00000000 | This register controls the operation of Enhancements to Scheduled Transmission (IEEE802.1Qbv) |
| GMAC_MTL_EST_Status | 0x0c58 | W | 0x00000000 | This register provides Status related to Enhancements to Scheduled Transmission |
| GMAC_MTL_EST_Sch_Error | 0x0c60 | W | 0x00000000 | This register provides the One Hot encoded Queue Numbers that are having the Scheduling related error (timeout) |
| GMAC_MTL_EST_Frm_Size_Error | 0x0c64 | W | 0x00000000 | This register provides the One Hot encoded Queue Numbers that are having the Frame |
| GMAC_MTL_EST_Frm_Size_Capture | 0x0c68 | W | 0x00000000 | This register captures the Frame Size and Queue Number of the first occurrence of the Frame Size related error. Up on clearing it captures the data of immediate next occurrence of a similar error |
| GMAC_MTL_EST_Intr_Enable | 0x0c70 | W | 0x00000000 | This register implements the Interrupt Enable bits for the various events that generate an interrupt. Bit positions have a 1 to 1 correlation with the status bit positions in MTL_ETS_Status |
| GMAC_MTL_EST_GCL_Control | 0x0c80 | W | 0x00000000 | This register provides the control information for reading/writing to the Gate Control lists |
| GMAC_MTL_EST_GCL_Data | 0x0c84 | W | 0x00000000 | This register holds the read data or write data in case of reads and writes respectively |
| GMAC_MTL_FPE_CTRL_STS | 0x0c90 | W | 0x00000000 | This register controls the operation of, and provides status for Frame Preemption (IEEE802.1Qbu/802.3br) |
| GMAC_MTL_FPE_Advance | 0x0c94 | W | 0x00000000 | This register holds the Hold and Release Advance time |

| Name | Offset | Size | Reset Value | Description |
|---|---|---|---|---|
| GMAC_MTL_TxQ0_Operation_Mode | 0x0d00 | W | 0x00060000 | The Queue 0 Transmit Operation Mode register establishes the Transmit queue operating modes and commands |
| GMAC_MTL_TxQ0_Underflow | 0x0d04 | W | 0x00000000 | The Queue 0 Underflow Counter register contains the counter for packets aborted because of Transmit queue underflow and packets missed because of Receive queue packet flush |
| GMAC_MTL_TxQ0_Debug | 0x0d08 | W | 0x00000000 | The Queue 0 Transmit Debug register gives the debug status of various blocks related to the Transmit queue |
| GMAC_MTL_TxQ0_ETS_Status | 0x0d14 | W | 0x00000000 | The Queue 0 ETS Status register provides the average traffic transmitted in Queue 0 |
| GMAC_MTL_TxQ0_Quantum_Weight | 0x0d18 | W | 0x00000000 | The Queue 0 Quantum or Weights register contains the quantum value for Deficit Weighted Round Robin (DWRR), weights for the Weighted Round Robin (WRR), and Weighted Fair Queuing (WFQ) for Queue 0 |
| GMAC_MTL_Q0_Interrupt_Ctrl_Status | 0x0d2c | W | 0x00000000 | This register contains the interrupt enable and status bits for the queue 0 interrupts |
| GMAC_MTL_RxQ0_Operation_Mode | 0x0d30 | W | 0x00000000 | The Queue 0 Receive Operation Mode register establishes the Receive queue operating modes and command |
| GMAC_MTL_RxQ0_Miss_Pkt_Ovf_Cnt | 0x0d34 | W | 0x00000000 | The Queue 0 Missed Packet and Overflow Counter register contains the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow |
| GMAC_MTL_RxQ0_Debug | 0x0d38 | W | 0x00000000 | The Queue 0 Receive Debug register gives the debug status of various blocks related to the Receive queue |
| GMAC_MTL_RxQ0_Control | 0x0d3c | W | 0x00000000 | The Queue Receive Control register controls the receive arbitration and passing of received packets to the application |
| GMAC_DMA_Mode | 0x1000 | W | 0x00000000 | The Bus Mode register establishes the bus operating modes for the DMA |

*Copyright 2022 © Rockchip Electronics Co., Ltd.*

| Name | Offset | Size | Reset Value | Description |
|---|---|---|---|---|
| GMAC_DMA_SysBus_Mode | 0x1004 | W | 0x00010000 | The System Bus mode register controls the behavior of the AHB or AXI master |
| GMAC_DMA_Interrupt_Status | 0x1008 | W | 0x00000000 | The application reads this Interrupt Status register during interrupt service routine or polling to determine the interrupt status of DMA channels, MTL queues, and the MAC |
| GMAC_DMA_Debug_Status0 | 0x100c | W | 0x00000000 | The Debug Status 0 register gives the Receive and Transmit process status for DMA Channel 0-Channel 2 for debugging purpose |
| GMAC_AXI_LPI_Entry_Interval | 0x1040 | W | 0x00000000 | This register is used to control the AXI LPI entry interval |
| GMAC_DMA_TBS_CTRL | 0x1050 | W | 0x00000000 | This register is used to control the TBS attributes |
| GMAC_DMA_CH0_Control | 0x1100 | W | 0x00000000 | The register specifies the MSS value for segmentation, length to skip between two descriptors, and 8xPBL mode |
| GMAC_DMA_CH0_Tx_Control | 0x1104 | W | 0x00000000 | The register controls the Tx features such as PBL, TCP segmentation, and Tx Channel weights |
| GMAC_DMA_CH0_Rx_Control | 0x1108 | W | 0x00000000 | The DMA Channel0 Receive Control register controls the Rx features such as PBL, buffer size, and extended status |
| GMAC_DMA_CH0_TxDesc_List_Address | 0x1114 | W | 0x00000000 | The Channel0 Tx Descriptor List Address register points the DMA to the start of Transmit |
| GMAC_DMA_CH0_RxDesc_List_Address | 0x111c | W | 0x00000000 | The Channel0 Rx Descriptor List Address register points the DMA to the start of Receive descriptor list |
| GMAC_DMA_CH0_TxDesc_Tail_Pointer | 0x1120 | W | 0x00000000 | The Channel0 Tx Descriptor Tail Pointer register points to an offset from the base and indicates the location of the last valid descriptor |
| GMAC_DMA_CH0_RxDesc_Tail_Pointer | 0x1128 | W | 0x00000000 | The Channel0 Rx Descriptor Tail Pointer Points to an offset from the base and indicates the location of the last valid descriptor |
| GMAC_DMA_CH0_TxDesc_Ring_Length | 0x112c | W | 0x00000000 | The Tx Descriptor Ring Length register contains the length of the Transmit descriptor ring |

Copyright 2022 © Rockchip Electronics Co., Ltd.

| Name | Offset | Size | Reset Value | Description |
|---|---|---|---|---|
| GMAC_DMA_CH0_RxDesc_Ring_Length | 0x1130 | W | 0x00000000 | The Channel0 Rx Descriptor Ring Length register contains the length of the Receive descriptor circular ring |
| GMAC_DMA_CH0_Interrupt_Enable | 0x1134 | W | 0x00000000 | The Channel0 Interrupt Enable register enables the interrupts reported by the Status register |
| GMAC_DMA_CH0_Rx_Interrupt_WD_Timer | 0x1138 | W | 0x00000000 | The Receive Interrupt Watchdog Timer register indicates the watchdog timeout for Receive Interrupt (RI) from the DMA |
| GMAC_DMA_CH0_Slot_Func_Ctrl_Status | 0x113c | W | 0x000007c0 | The Slot Function Control and Status register contains the control bits for slot function and the status for Transmit path |
| GMAC_DMA_CH0_Current_App_TxDesc | 0x1144 | W | 0x00000000 | The Channel0 Current Application Transmit Descriptor register points to the current Transmit descriptor read by the DMA |
| GMAC_DMA_CH0_Current_App_RxDesc | 0x114c | W | 0x00000000 | The Channel0 Current Application Receive Descriptor register points to the current Receive descriptor read by the DMA |
| GMAC_DMA_CH0_Current_App_TxBuffer | 0x1154 | W | 0x00000000 | The Channel0 Current Application Transmit Buffer Address register points to the current Tx buffer address read by the DMA |
| GMAC_DMA_CH0_Current_App_RxBuffer | 0x115c | W | 0x00000000 | The Channel0 Current Application Receive Buffer Address register points to the current Rx buffer address read by the DMA |
| GMAC_DMA_CH0_Status | 0x1160 | W | 0x00000000 | The software driver (application) reads the Status register during interrupt service routine or polling to determine the status of the DMA |
| GMAC_DMA_CH0_Miss_Frame_Cnt | 0x1164 | W | 0x00000000 | This register has the number of packet counter that got dropped by the DMA either due to Bus Error or due to programming RPF field in DMA_CH0_Rx_Control register |
| GMAC_DMA_CH0_RX_ERI_Cnt | 0x1168 | W | 0x00000000 | The DMA_CH0_RX_ERI_Cnt registers provides the count of the number of times ERI was asserted |

| 31 | RW | 0x0 | ARPEN<br>ARP Offload Enable<br>When this bit is set, the MAC can recognize an incoming ARP request packet and schedules the ARP packet for transmission. It forwards the ARP packet to the application and also indicate the events in the RxStatus. When this bit is reset, the MAC receiver does not recognize any ARP packet and indicates them as Type frame in the RxStatus.<br>This bit is available only when the Enable IPv4 ARP Offload is selected.<br>Values:<br>1'b0: ARP Offload is disabled<br>1'b1: ARP Offload is enabled |
| 30:28 | RW | 0x0 | SARC<br>Source Address Insertion or Replacement Control<br>This field controls the source address insertion or replacement for all transmitted packets. Bit 30 specifies which MAC Address register (0 or 1) is used for source address insertion or replacement based on the values of Bits[29:28]:<br>2'b0x:<br>The mti_sa_ctrl_i and ati_sa_ctrl_i input signals control the SA field generation.<br>2'b10:<br>1.If Bit 30 is set to 0, the MAC inserts the content of the MAC Address 0 registers in the SA field of all transmitted packets.<br>2.If Bit 30 is set to 1 and the Enable MAC Address Register 1 option is selected while configuring the core, the MAC inserts the content of the MAC Address 1 registers in the SA field of all transmitted packets.<br>2'b11:<br>1.If Bit 30 is set to 0, the MAC replaces the content of the MAC Address 0 registers in the SA field of all transmitted packets.<br>2.If Bit 30 is set to 1 and the MAC Address Register 1 is enabled, the MAC replaces the content of the MAC Address 1 registers in the SA field of all transmitted packets.<br>Note: Changes to this field take effect only on the start of a packet. If you write to this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value.<br>0x0 (SA_CTRL_IN): mti_sa_ctrl_i and ati_sa_ctrl_i input signals control the SA field generation<br>0x2 (MAC0_INS_SA): Contents of MAC Addr-0 inserted in SA field<br>0x3 (MAC0_REP_SA): Contents of MAC Addr-0 replaces SA field<br>0x6 (MAC1_INS_SA): Contents of MAC Addr-1 inserted in SA field<br>0x7 (MAC1_REP_SA): Contents of MAC Addr-1 replaces SA field |

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 27 | RW | 0x0 | IPC<br>Checksum Offload<br>When set, this bit enables the IPv4 header checksum checking and IPv4 or IPv6 TCP, UDP, or ICMP payload checksum checking. When this bit is reset, the COE function in the receiver is disabled.The Layer 3 and Layer 4 Packet Filter and Enable Split Header features automatically selects the IPC Full Checksum Offload Engine on the Receive side. When any of these features are enabled, you must set the IPC bit.<br>Values:<br>1'b0: IP header/payload checksum checking is disabled<br>1'b1: IP header/payload checksum checking is enabled |
| 26:24 | RW | 0x0 | IPG<br>Inter-Packet Gap<br>These bits control the minimum IPG between packets during transmission. This range of minimum IPG is valid in full-duplex mode.In the half-duplex mode, the minimum IPG can be configured only for 64-bit times (IPG = 100). Lower values are not considered. When a JAM pattern is being transmitted because of backpressure activation, the MAC does not consider the minimum IPG.The above function (IPG less than 96 bit times) is valid only when EIPGEN bit in MAC_Ext_Configuration register is reset. When EIPGEN is set, then the minimum IPG (greater than 96 bit times) is controlled as per the description given in EIPG field in MAC_Ext_Configuration register.<br>Values:<br>3'b000: 96 bit times IPG<br>3'b001: 88 bit times IPG<br>3'b010: 80 bit times IPG<br>3'b011: 72 bit times IPG<br>3'b100: 64 bit times IPG<br>3'b101: 56 bit times IPG<br>3'b110: 48 bit times IPG<br>3'b111: 40 bit times IPG |
| 23 | RW | 0x0 | GPSLCE<br>Giant Packet Size Limit Control Enable<br>When this bit is set, the MAC considers the value in GPSL field in MAC_Ext_Configuration register to declare a received packet as Giant packet. This field must be programmed to more than 1,518 bytes. Otherwise, the MAC considers 1,518 bytes as giant packet limit. When this bit is reset, the MAC considers a received packet as Giant packet when its size is greater than 1,518 bytes (1522 bytes for tagged packet).The watchdog timeout limit, Jumbo Packet Enable and 2K Packet Enable have higher precedence over this bit, that is the MAC considers a received packet as Giant packet when its size is greater than 9,018 bytes (9,022 bytes for tagged packet) with Jumbo Packet Enabled and greater than 2,000 bytes with 2K Packet Enabled. The watchdog timeout, if enabled, terminates the received packet when watchdog limit is reached. Therefore, the programmed giant packet limit should be less than the watchdog limit to get the giant packet status.<br>Values:<br>1'b0: Giant Packet Size Limit Control is disabled<br>1'b1: Giant Packet Size Limit Control is enabled |

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 6:5 | RW | 0x0 | BL<br>Back-Off Limit<br>The back-off limit determines the random integer number (r) of slot time delays (4,096 bit times for 1000/2500 Mbps; 512 bit times for 10/100 Mbps) for which the MAC waits before rescheduling a transmission attempt during retries after a collision. n = retransmission attempt.<br>The random integer r takes the value in the range 0 <= r < 2^k<br>This bit is applicable only in the half-duplex mode.<br>Values:<br>2'b00: k = min(n,10)<br>2'b01: k = min(n,8)<br>2'b10: k = min(n,4)<br>2'b11: k = min(n,1) |
| 4 | RW | 0x0 | DC<br>Deferral Check<br>When this bit is set, the deferral check function is enabled in the MAC. The MAC issues a Packet Abort status, along with the excessive deferral error bit set in the Tx packet status, when the Tx state machine is deferred for more than 24,288 bit times in 10 or 100 Mbps mode. If the MAC is configured for 1000/2500 Mbps operation, the threshold for deferral is 155,680 bits times. Deferral begins when the transmitter is ready to transmit, but it is prevented<br>because of an active carrier sense signal (CRS) on GMII or MII. The defer time is not cumulative. For example, if the transmitter defers for 10,000 bit times because the CRS signal is active and the CRS signal becomes inactive, the transmitter transmits and collision happens. Because of collision, the transmitter needs to back off and then defer again after back off completion. In such a scenario, the deferral timer is reset to 0, and it is restarted. When this bit is reset, the deferral check function is disabled and the MAC defers until the CRS signal goes inactive. This bit is applicable only in the half-duplex mode.<br>Values:<br>1'b0: Deferral check function is disabled<br>1'b1: Deferral check function is enabled |
| 3:2 | RW | 0x0 | PRELEN<br>Preamble Length for Transmit packets<br>These bits control the number of preamble bytes that are added to the beginning of every Tx packet. The preamble reduction occurs only when the MAC is operating in the full-duplex mode.<br>Values:<br>2'b00: 7 bytes of preamble<br>2'b01: 5 bytes of preamble<br>2'b10: 3 bytes of preamble<br>2'b11: Reserved |

If the length of a received packet exceeds the value of this field, such packet is terminated and declared as an error packet.<br>Note: When the PWE bit is set, the value in this field should be more than 1,522 (0x05F2). Otherwise, the IEEE 802.3-specified valid tagged packets are declared as error packets and then dropped.<br>Values:<br>4'b0000: 2 KB<br>4'b0001: 3 KB<br>4'b0010: 4 KB<br>4'b0011: 5 KB<br>4'b0100: 6 KB<br>4'b0101: 7 KB<br>4'b0110: 8 KB<br>4'b0111: 9 KB<br>4'b1000: 10 KB<br>4'b1001: 11 KB<br>4'b1010: 12 KB<br>4'b1011: 13 KB<br>4'b1100: 14 KB<br>4'b1101: 15 KB<br>4'b1110: 16383 Bytes<br>4'b1111: Reserved |

**GMAC_MAC_Hash_Table_Reg0**

Address: Operational Base + offset (0x0010)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:0 | RW | 0x00000000 | HT31T0<br>MAC Hash Table First 32 Bits<br>This field contains the first 32 Bits [31:0] of the Hash table. The Hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper six (seven in 128-bit Hash or eight in 256-bit Hash) bits of the CRC register are used to index the content of the Hash table. The most significant bits determines the register to be used (Hash Table Register X), and the least significant five bits determine the bit within the register. For example, a hash value of 6'b100000 (in 64-bit Hash) selects Bit 0 of the Hash Table Register 1, a value of 7b'1110000 (in 128-bit Hash) selects Bit 16 of the Hash Table Register 3 and a value of 8b'10111111 (in 256-bit Hash) selects Bit 31 of the Hash Table Register 5.<br>The hash value of the destination address is calculated in the following way:<br>1. Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).<br>2. Perform bitwise reversal for the value obtained in Step 1.<br>3. Take the upper 6 (or 7 or 8) bits from the value obtained in Step 2. If the corresponding bit value of the register is 1'b1, the packet is accepted. Otherwise, it is rejected. If the PM bit is set in MAC_Packet_Filter, all multicast packets are accepted regardless of the multicast hash values.<br>If the Hash Table register is configured to be double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Hash Table Register X registers are written.If double-synchronization is enabled, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain. |

|---|---|---|---|
| 1 | RW | 0x0 | UP<br>Unicast Pause Packet Detect<br>A pause packet is processed when it has the unique multicast address specified in the IEEE 802.3. When this bit is set, the MAC can also detect Pause packets with unicast address of the station. This unicast address should be as specified in MAC_Address0_High and MAC_Address0_Low. When this bit is reset, the MAC only detects Pause packets with unique multicast address.<br>Note: The MAC does not process a Pause packet if the multicast address is different from the unique multicast address. This is also applicable to the received PFC packet when the Priority Flow Control (PFC) is enabled. The unique multicast address (0x01_80_C2_00_00_01) is as specified in IEEE 802.1 Qbb-2011.<br>Values:<br>1'b0: Unicast Pause Packet Detect disabled<br>1'b1: Unicast Pause Packet Detect enabled |
| 0 | RW | 0x0 | RFE<br>Receive Flow Control Enable<br>When this bit is set and the MAC is operating in full-duplex mode, the MAC decodes the received Pause packet and disables its transmitter for a specified (Pause) time. When this bit is reset or the MAC is operating in half-duplex mode, the decode function of the Pause packet is disabled. When PFC is enabled, flow control is enabled for PFC packets. The MAC decodes the received PFC packet and disables the Transmit queue, with matching priorities, for a duration of received Pause time.<br>Values:<br>1'b0: Receive Flow Control is disabled<br>1'b1: Receive Flow Control is enabled |

|---|---|---|---|
| 31:0 | RW | 0x00000000 | WKUPFRMFTR(cont.)<br>(4) If filters chained by And_Previous bit setting have complementary programming, then a frame may never pass the AND chained filter. For example, if Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set), Filter 1 Address_Type bit is set (bit 3 in Filter 1 command is set) indicating multicast detection and Filter 2 Address_Type bit is reset (bit 3 in Filter 2 command is reset) indicating unicast detection or vice versa, a remote wakeup frame does not pass the AND chained filter as a remote wakeup frame cannot be of both unicast and multicast address type.<br>4. Bit 0 is the enable for filter i. If Bit 0 is not set, filter i is disabled.<br>Filter i Byte Mask: The filter i byte mask register defines the bytes of the packet that are examined by filter i (0, 1, 2, 3, .., 15) to determine whether or not a packet is a wake-up packet.<br>1. The MSB (31st bit) must be zero.<br>2. Bit j[30:0] is the byte mask.<br>3. If Bit j (byte number) of the byte mask is set, the CRC block processes the Filter i Offset + j of the incoming packet; otherwise Filter i Offset + j is ignored.<br>Filter i Offset: The filter i offset register defines the offset (within the packet) from which the filter i examines the packets.<br>1. This 8-bit pattern-offset is the offset for the filter i first byte to be examined.<br>2. The minimum allowed offset is 12, which refers to the 13th byte of the packet.<br>3. The offset value 0 refers to the first byte of the packet.<br>Filter i CRC-16: The filter i CRC-16 register contains the CRC-16 value calculated from the pattern and the byte mask programmed in the Remote Wakeup filter register.<br>1. The 16-bit CRC calculation uses the following polynomial: G(x) = x^16 + x^15 + x^2 + 1<br>2. Each mask, used in the hash function calculation, is compared with a 16-bit value associated with that mask. Each filter has the following:<br>(1)32-bit Mask: Each bit in this mask corresponds to one byte in the detected packet. If the bit is 1, the corresponding byte is taken into the CRC16 calculation.<br>(2) 8-bit Offset Pointer: Specifies the byte to start the CRC-16 computation. The pointer and the mask are used together to locate the bytes to be used in the CRC-16 calculations. |

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:0 | RW | 0x00000000 | WKUPFRMFTR<br>RWK Packet Filter<br>This field contains the various controls of RWK Packet filter.<br>When the Remote Wakeup Filters are to be programmed, the entire set of wkuppktfilter_reg registers must be written. The wkuppktfilter_reg register is programmed by sequentially writing the eight, sixteen or thirty-two register values in MAC_RWK_Packet_Filter register for wkuppktfilter_reg0, wkuppktfilter_reg1, ..., wkuppktfilter_reg31 respectively. The wkuppktfilter_reg register is read in a similar way.<br>The MAC updates the wkuppktfilter_reg register current pointer value in RWKPTR field of MAC_PMT_Control_Status register.<br>The Remote Wakeup Filters are arranged in blocks of 4 filters each and each such block have eight 32-bit wide registers, viz. wkuppktfilter_reg0-7, wkuppktfilter_reg8-15, wkuppktfilter_reg16-23 and wkuppktfilter_reg24-31. The fields of Remote Wakeup Filter are described as follows:<br>Filter i Command: The 4-bit filter i command controls the filter i operation.<br>1. Bit 3 specifies the address type, defining the destination address type of the pattern. When the bit is set, the pattern applies to only multicast packets; when the bit is reset, the pattern applies only to unicast packet.<br>2. Bit 2 (Inverse Mode), when set, reverses the logic of the CRC16 hash function signal, to reject a packet with matching CRC-16 value. Bit 2, along with Bit 1, allows a MAC to reject a subset of remote wake-up packets by creating filter logic such as "Pattern 1 AND NOT Pattern 2".<br>3. Bit 1 (And_Previous) implements the Boolean logic. When set, the result of the current entry is logically ANDed with the result of the previous filter. This AND logic allows a filter pattern longer than 32 bytes by splitting the mask among two, three, or four filters. This depends on the number of filters that have the And_Previous bit set. The details are provided below:<br>(1) The And_Previous bit setting is applicable within a set of 4 filters.<br>(2) Setting of And_Previous bit of filter that is not enabled has no effect, that is setting And_Previous bit of lowest number filter in the set of 4 filters has no effect. For example, setting of And_Previous bit of Filter 0 has no effect.<br>(3) If And_Previous bit is set for filter to form AND chained filter, the AND chain breaks at the point any filter is not enabled. For example: If Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set) but Filter 1 is not enabled (bit 0 in Filter 1 command is reset), then only Filter 2 result is considered. If Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set), Filter 3 And_Previous bit is set (bit 1 in Filter 3 command is set), but Filter 1 is not enabled (bit 0 in Filter 1 command is reset), then only Filter 2 result ANDed with Filter 3 result is considered. If Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set), Filter 3 And_Previous bit is set (bit 1 in Filter 3 command is set), but Filter 2 is not enabled (bit 0 in Filter 2 command is reset), then since setting of Filter 2 And_Previous bit has no effect only Filter 1 result ORed with Filter 3 result is considered. |

|---|---|---|---|
| 25:16 | RW | 0x3e8 | LST<br>LPI LS Timer<br>This field specifies the minimum time (in milliseconds) for which the link status from the PHY should be up (OKAY) before the LPI pattern can be transmitted to the PHY. The MAC does not transmit the LPI pattern even when the LPIEN bit is set unless the LPI LS Timer reaches the programmed terminal count. The default value of the LPI LS Timer is 1000 (1 sec) as defined in the IEEE standard. |
| 15:0 | RW | 0x0000 | TWT<br>LPI TW Timer<br>This field specifies the minimum time (in microseconds) for which the MAC waits after it stops transmitting the LPI pattern to the PHY and before it resumes the normal transmission. The TLPIEX status bit is set after the expiry of this timer. |

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 25:21 | RW | 0x00 | PA<br>Physical Layer Address<br>This field indicates which Clause 22 PHY devices (out of 32 devices) the MAC is accessing. For RevMII, this field gives the PHY Address of the RevMII module. This field indicates which Clause 45 capable PHYs (out of 32 PHYs) the MAC is accessing. |
| 20:16 | RW | 0x00 | RDA<br>Register/Device Address<br>These bits select the PHY register in selected Clause 22 PHY device. For RevMII, these bits select the CSR register in the RevMII Registers set. These bits select the Device (MMD) in selected Clause 45 capable PHY. |
| 15 | RO | 0x0 | reserved |
| 14:12 | RW | 0x0 | NTC<br>Number of Trailing Clocks<br>This field controls the number of trailing clock cycles generated on gmii_mdc_o (MDC) after the end of transmission of MDIO frame. The valid values can be from 0 to 7. Programming the value to 3'h3 indicates that there are additional three clock cycles on the MDC line after the end of MDIO frame transfer. |
| 11:8 | RW | 0x0 | CR<br>CSR Clock Range<br>The CSR Clock Range selection determines the frequency of the MDC clock according to the CSR clock frequency used in your design:<br>4'b0000: CSR clock = 60-100 MHz; MDC clock = CSR clock/42<br>4'b0001: CSR clock = 100-150 MHz; MDC clock = CSR clock/62<br>4'b0010: CSR clock = 20-35 MHz; MDC clock = CSR clock/16<br>4'b0011: CSR clock = 35-60 MHz; MDC clock = CSR clock/26<br>4'b0100: CSR clock = 150-250 MHz; MDC clock = CSR clock/102<br>4'b0101: CSR clock = 250-300 MHz; MDC clock = CSR clock/124<br>4'b0110: CSR clock = 300-500 MHz; MDC clock = CSR clock/204<br>4'b0111: CSR clock = 500-800 MHz; MDC clock = CSR clock/324<br>The suggested range of CSR clock frequency applicable for each value (when Bit 11 = 0) ensures that the MDC clock is approximately between 1.0 MHz to 2.5 MHz frequency range. When Bit 11 is set, you can achieve a higher frequency of the MDC clock than the frequency limit of 2.5 MHz (specified in the IEEE 802.3) and program a clock divider of lower value. For example, when CSR clock is of 100 MHz frequency and you program these bits as 1010, the resultant MDC clock is of 12.5 MHz which is above the range specified in IEEE 802.3. Program the following values only if the interfacing chips support faster MDC clocks:<br>4'b1000: CSR clock/4<br>4'b1001: CSR clock/6<br>4'b1010: CSR clock/8<br>4'b1011: CSR clock/10<br>4'b1100: CSR clock/12<br>4'b1101: CSR clock/14<br>4'b1110: CSR clock/16<br>4'b1111: CSR clock/18<br>These bits are not used for accessing RevMII. These bits are read-only if the RevMII interface is selected as single PHY interface. |

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 3:0 | RW | 0x0 | PPSCTRL_PPSCMD<br>PPS Output Frequency Control<br>This field controls the frequency of the PPS0 output (ptp_pps_o[0]) signal. The default value of PPSCTRL is 0000, and the PPS output is 1 pulse (of width clk_ptp_i) every second. For other values of PPSCTRL, the PPS output becomes a generated clock of following frequencies:<br>4'b0001: The binary rollover is 2 Hz, and the digital rollover is 1 Hz.<br>4'b0010: The binary rollover is 4 Hz, and the digital rollover is 2 Hz.<br>4'b0011: The binary rollover is 8 Hz, and the digital rollover is 4 Hz.<br>4'b0100: The binary rollover is 16 Hz, and the digital rollover is 8 Hz.<br>...<br>4'b1111: The binary rollover is 32.768 KHz and the digital rollover is 16.384 KHz.<br>Note:<br>In the binary rollover mode, the PPS output (ptp_pps_o) has a duty cycle of 50 percent with these frequencies. In the digital rollover mode, the PPS output frequency is an average number. The actual clock is of different frequency that gets synchronized every second. For example:<br>1. When PPSCTRL = 0001, the PPS (1 Hz) has a low period of 537 ms and a high period of 463 ms.<br>2. When PPSCTRL = 0010, the PPS (2 Hz) is a sequence of One clock of 50 percent duty cycle and 537 ms period Second clock of 463 ms period (268 ms low and 195 ms high).<br>3. When PPSCTRL = 0011, the PPS (4 Hz) is a sequence of Three clocks of 50 percent duty cycle and 268 ms period Fourth clock of 195 ms period (134 ms low and 61 ms high).<br>This behavior is because of the non-linear toggling of bits in the digital rollover mode in the MAC_System_Time_Nanoseconds register. |

| 0 | RO | 0x0 | ABS<br>Average Bits per Slot<br>This field contains the average transmitted bits per slot. When the DCB operation is enabled for Queue 0, this field is computed over every 10 million bit times slot (4 ms in 2500 Mbps; 10 ms in 1000 Mbps; 100 ms in 100 Mbps). The maximum value is 0x989680. |

**GMAC_MTL_TxQ1_Quantum_Weight**

*Copyright 2022 © Rockchip Electronics Co., Ltd.*

Address: Operational Base + offset (0x0d58)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:21 | RO | 0x000 | reserved |
| 20:0 | RW | 0x000000 | ISCQW<br>idleSlopeCredit, Quantum or Weights<br>1.idleSlopeCredit<br>When AV feature is enabled, this field contains the idleSlopeCredit value required for the credit-based shaper algorithm for Queue 1. This is the rate of change of credit in bits per cycle (40 ns for 100 Mbps; 8 ns for 1000 Mbps; 3.2 ns for 2500 Mbps) when the credit is increasing. The software should program this field with computed credit in bits per cycle scaled by 1,024. The maximum value is portTransmitRate, that is, 0x2000 in 1000/2500 Mbps mode and 0x1000 in 100 Mbps mode. Bits[20:14] must be written to zero.<br>2.Quantum<br>When the DCB operation is enabled with DWRR algorithm for Queue 1 traffic, this field contains the quantum value in bytes to be added to credit during every queue scanning cycle. The maximum value is 0x1312D0 bytes.<br>3.Weights<br>When DCB operation is enabled with WFQ algorithm for Queue 1 traffic, this field contains the weight for this queue. The maximum value is 0x3FFF where weight of 0 indicates 100% bandwidth. Bits[20:14] must be written to zero. When DCB operation or generic queuing operation is enabled with WRR algorithm for Queue 1 traffic, this field contains the weight for this queue. The maximum value is 0x64. Bits [20:7] must be written to zero.<br><br>Note 1: In multiple Queue configuration this field in respective per queue register must be programmed to some non-zero value when multiple queues are enabled or single queue other than Q0 is enabled. This field need not be programmed when only Q0 is enabled. In general, when WRR algorithm is selected a non-zero value must be programmed on both Receive and Transmit. In Receive, the register is MTL_Operation_Mode register.<br>Note 2: For WFQ algorithm, higher the programmed weights lesser the bandwidth allocated for that Transmit Queue. The finish time is not a function of particular packet alone but it is as per the formula: (previous_finish_time of particular Transmit Queue + (weights*packet_size))<br>Note 3: The weights programmed do not correspond to the number of packets but the fraction of bandwidth or time allocated for particular queue w.r.t. total BW or time. |

# 25.6 Application Note

## 25.6.1 Descriptors

The DMA engine uses descriptors to efficiently move data from source to destination with minimal application CPU intervention. The DMA is designed for packet-oriented data transfers such as packets in Ethernet. The DMA controller can be programmed to interrupt the application CPU for situations such as Packet Transmit and Receive Transfer completion, and other normal or error conditions.

The DMA and the application communicate through the following two data structures:

- Control and Status registers (CSR)
- Descriptor lists and data buffers

The base address of each list is written to the respective Tx Descriptor List Address register and Rx Descriptor List Address register. The descriptor list is forward linked and the next descriptor is always considered at a fixed offset to the current one. The offset is controlled by the DSL field of DMA_Ch[n]_Control register. The number of descriptors in the list is programmed in the respective Tx (or Rx) Descriptor Ring Length register. Once the DMA processes the last descriptor in the list, it automatically jumps back to the descriptor in the List Address register to create a descriptor ring.

The descriptor lists reside in the physical memory address space of the application. Each descriptor can point to a maximum of two buffers in the system memory. This enables two buffers to be used, physically addressed, rather than contiguous buffers in memory.

A data buffer resides in the application physical memory space and consists of an entire packet or part of a packet but cannot exceed a single packet. Buffers contain only data. Buffer status is maintained in the descriptor. Data chaining refers to packets that span multiple data buffers. However, a single descriptor cannot span multiple packets. The DMA skips to the data buffer of next packet when EOP is detected.

The GMAC supports the following two types of descriptors:

- Normal Descriptor: Normal descriptors are used for packet data and to provide control information applicable to the packets to be transmitted
- Context Descriptor: Context descriptors are used to provide control information applicable to the packet to be transmitted

The GMAC supports the ring structure for the DMA descriptor.

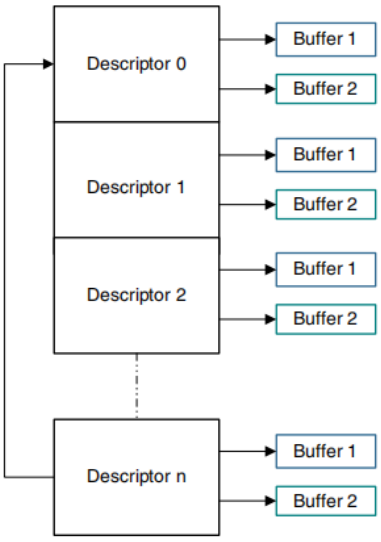

Fig. 25-10 Descriptor Ring Structure

In Ring structure, descriptors are separated by the Word, DWord, or LWord number programmed in the DSL field of the DMA_CH#_Control register. The application needs to program the total ring length, that is, the total number of descriptors in ring span in the following registers of a DMA channel:

- Transmit Descriptor Ring Length Register (DMA_CH#_TxDesc_Ring_Length)
- Receive Descriptor Ring Length Register (DMA_CH#_RxDesc_Ring_Length)

Copyright 2022 © Rockchip Electronics Co., Ltd.

The Descriptor Tail Pointer Register contains the pointer to the descriptor address (N). The base address and the current descriptor pointer decide the address of the current descriptor that the DMA can process.
The descriptors up to one location less than the one indicated by the descriptor tail pointer (N – 1) are owned by the DMA. The DMA continues to process the descriptors until the following condition occurs:

Current Descriptor Pointer == Descriptor Tail Pointer

The DMA goes into the Suspend mode when this condition occurs. The application must perform a write to the Descriptor Tail pointer register and update the tail pointer so that the following condition is true:

Current Descriptor Pointer < Descriptor Tail Pointer

The DMA automatically wraps around the base address when the end of ring is reached.
For descriptors owned by the application, the OWN bit of DES3 is reset to 0. For descriptors owned by the DMA, the OWN bit is set to 1. If the application has only one descriptor in the beginning, the application sets the last descriptor address (tail pointer) to Descriptor Base Address + 1. The DMA processes the first descriptor and then waits for the application to advance the tail pointer.

## 25.6.2 Transmit Descriptors

The DMA in GMAC requires at least one descriptor for a transmit packet. In addition to two buffers, two byte-count buffers, and two address pointers, the transmit descriptor has control fields which can be used to control the MAC operation on per-transmit packet basis. The Transmit Normal descriptor has two formats: Read format and Write-Back format.

## 25.6.3 Transmit Normal Descriptor (Read Format)

Table 25-5 TDES0 Normal Descriptor (Read Format)

| Bit | Name | Description |
|---|---|---|
| 31:0 | BUF1AP | Buffer 1 Address Pointer or TSO Header Address Pointer<br>These bits indicate the physical address of Buffer 1.<br>These bits indicate the TSO Header Address pointer when the following bits are set:<br>■ TSE bit of TDES3<br>■ FD bit of TDES3 |

Table 25-6 TDES1 Normal Descriptor (Read Format)

| Bit | Name | Description |
|---|---|---|
| 31:0 | BUF2AP | Buffer 2 or Buffer 1 Address Pointer<br>This bit indicates the physical address of Buffer 2 when a descriptor ring structure is used. There is no limitation for the buffer address alignment.<br>In 40- or 48-bit addressing mode, these bits indicate the most-significant 8- or 16- bits of the Buffer 1 Address Pointer. |

Table 25-7 TDES2 Normal Descriptor (Read Format)

| Bit | Name | Description |
|---|---|---|
| 31 | IOC | Interrupt on Completion<br>This bit controls the setting of TI and ETI status bits in the DMA_CH#_Status register. When ETIC = 1 and TDES2[LD] = 0, this bit sets the ETI bit. When TDES3[LD] = 1, this bit sets the TI status bit. |
| 30 | TTSE/TMWD | Transmit Timestamp Enable or External TSO Memory Write Enable<br>This bit enables the IEEE1588 time stamping for Transmit packet referenced by the descriptor, if TSE bit is not set.<br>If TSE bit is set and external TSO memory is enabled, setting this bit disables external TSO memory writing for this packet. |

Copyright 2022 © Rockchip Electronics Co., Ltd.

| Bit | Name | Description |
|---|---|---|
| 29:16 | B2L | Buffer 2 Length<br>The driver sets this field. When set, this field indicates Buffer 2 length |
| 15:14 | VTIR | VLAN Tag Insertion or Replacement<br>These bits request the MAC to perform VLAN tagging or untagging before transmitting the packets. The application must set the CRC Pad Control bits appropriately when VLAN Tag Insertion, Replacement, or Deletion is enabled for the packet. The following list describes the values of these bits:<br>■ 2'b00: Do not add a VLAN tag.<br>■ 2'b01: Remove the VLAN tag from the packets before transmission. This option should be used only with the VLAN packets.<br>■ 2'b10: Insert a VLAN tag with the tag value programmed in the MAC_VLAN_Incl register or context descriptor.<br>■ 2'b11: Replace the VLAN tag in packets with the tag value programmed in the MAC_VLAN_Incl register or context descriptor. This option should be used only with the VLAN packets.<br>These bits are valid when the Enable SA and VLAN Insertion on Tx option is selected while configuring the core |
| 13:0 | HL or B1L | Header Length or Buffer 1 Length<br>For Header length only bits [9:0] are taken. The size 13:0 is applicable only when interpreting buffer 1 length.<br>If the TCP Segmentation Offload feature is enabled through the TSE bit of TDES3, this field is equal to the header length. When the TSE bit is set in TDES3, the header length includes the length in bytes from Ethernet Source address till the end of the TCP header. The maximum header length supported for TSO feature is 1023 bytes. The maximum header length supported for TSO feature is 1023 bytes.<br>If the TCP Segmentation Offload feature is not enabled, this field is equal to Buffer 1 length. |

Table 25-8 TDES3 Normal Descriptor (Read Format)

| Bit | Name | Description |
|---|---|---|
| 31 | OWN | Own Bit<br>When this bit is set, it indicates that the DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit after it completes the transfer of data given in the associated buffer(s). |
| 30 | CTXT | Context Type<br>This bit should be set to 1'b0 for normal descriptor. |
| 29 | FD | First Descriptor<br>When this bit is set, it indicates that the buffer contains the first segment of a packet. |
| 28 | LD | Last Descriptor<br>When this bit is set, it indicates that the buffer contains the last segment of the packet. When this bit is set, the B1L or B2L field should have a non-zero value. |
| 27:26 | CPC | CRC Pad Control<br>This field controls the CRC and Pad Insertion for Tx packet. This field is valid only when the first descriptor bit (TDES3[29]) is set. The following list describes the values of Bits[27:26]:<br>■ 2'b00: CRC and Pad Insertion. The MAC appends the cyclic redundancy check (CRC) at the end of the transmitted packet of length greater than or equal to 60 bytes. The MAC automatically appends padding and CRC to a packet with length less than 60 bytes. |

| Bit | Name | Description |
|---|---|---|
| | | ■ 2'b01: CRC Insertion (Disable Pad Insertion). The MAC appends the CRC at the end of the transmitted packet but it does not append padding. The application should ensure that the padding bytes are present in the packet being transferred from the Transmit Buffer, that is, the packet being transferred from the Transmit Buffer is of length greater than or equal to 60 bytes.<br>■ 2'b10: Disable CRC Insertion. The MAC does not append the CRC at the end of the transmitted packet. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the Transmit Buffer.<br>■ 2'b11: CRC Replacement. The MAC replaces the last four bytes of the transmitted packet with recalculated CRC bytes. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the Transmit Buffer.<br>This field is valid only for the first descriptor.<br>Note: When the TSE bit is set, the MAC ignores this field because the CRC and pad insertion is always done for segmentation. |
| 25:23 | SAIC | SA Insertion Control<br>These bits request the MAC to add or replace the Source Address field in the Ethernet packet with the value given in the MAC Address 0 register. The application must set the CRC Pad Control bits appropriately when SA Insertion Control is enabled for the packet. Bit 25 specifies the MAC Address Register (1 or 0) value that is used for Source Address insertion or replacement.<br>The following list describes the values of Bits[24:23]:<br>■ 2'b00: Do not include the source address<br>■ 2'b01: Include or insert the source address. For reliable transmission, the application must provide frames without source addresses.<br>■ 2'b10: Replace the source address. For reliable transmission, the application must provide frames with source addresses.<br>■ 2'b11: Reserved<br>These bits are valid in the EQOS-DMA, EQOS-AXI, and EQOS-AHB configurations when the Enable SA and VLAN Insertion on Tx option is selected while configuring the core and when the First Segment control bit (TDES3 [29]) is set.<br>This field is valid only for the first descriptor. |
| 22:19 | SLOTNUM or THL | SLOTNUM: Slot Number Control Bits in AV Mode<br>These bits indicate the slot interval in which the data should be fetched from the corresponding buffers addressed by TDES0 or TDES1. When the Transmit descriptor is fetched, the DMA compares the slot number value in this field<br>with the slot interval maintained in the RSN field DMA_CH#_Slot_Function_Control_Status. It fetches the data from the buffers only if a value matches. These bits are valid only for the AV channels.<br>THL: TCP/UDP Header Length<br>If the TSE bit is set, this field contains the length of the TCP/UDP header. The minimum value of this field must be 5 for TCP header. The value must be equal to 2 for UDP header.<br>This field is valid only for the first descriptor. |
| 18 | TSE | TCP Segmentation Enable<br>When this bit is set, the DMA performs the TCP/UDP segmentation or UDP fragmentation for a packet depending on the TSE_MODE[1:0] bit of the DMA_CH(#i)_Tx_Control Register. This bit is valid only if the FD bit is set. |

Copyright 2022 © Rockchip Electronics Co., Ltd.

| Bit | Name | Description |
|---|---|---|
| 17:16 | CIC/TPL | Checksum Insertion Control or TCP Payload Length<br>These bits control the checksum calculation and insertion. The following list describes the bit encoding:<br>■ 2'b00: Checksum Insertion Disabled.<br>■ 2'b01: Only IP header checksum calculation and insertion are enabled.<br>■ 2'b10: IP header checksum and payload checksum calculation and insertion are enabled, but pseudo-header checksum is not calculated in hardware.<br>■ 2'b11: IP Header checksum and payload checksum calculation and insertion are enabled, and pseudo-header checksum is calculated in hardware. This field is valid when the Enable Transmit TCP/IP Checksum Offload option is selected and the TSE bit is reset.<br>When the TSE bit is set, this field contains the upper bits [17:16] of the TCP Payload (or IP Payload for UDP fragmentation). This allows the TCP/UDP packet length field to be spanned across TDES3[17:0] to provide 256 KB packet length support.<br>This field is valid only for the first descriptor. |
| 15 | TPL | Reserved or TCP Payload Length<br>When the TSE bit is reset, this bit is reserved. When the TSE bit is set, this is Bit 15 of the TCP payload length [17:0]. This field is valid only when the Enable TCP Segmentation Offloading for TCP/IP Packets option is selected while configuring the core. |
| 14:0 | FL/TPL | Frame Length or TCP Payload Length<br>This field is equal to the length of the packet to be transmitted in bytes. When the TSE bit is not set, this field is equal to the total length of the packet to be transmitted:<br>Ethernet Header Length + TCP /IP Header Length – Preamble Length – SFD Length + Ethernet Payload Length<br>When the TSE bit is set, this field is equal to the lower 15 bits of the TCP payload length in case of segmentation and IP payload in case of UDP fragmentation. In case of segmentation, this length does not include Ethernet header or TCP/UDP/IP header length. In case of fragmentation, this length does not include Ethernet header and IP header. When DWRR/WFQ algorithm is NOT enabled, value written into this field is not used when TSE = 0. |

### 25.6.4 Transmit Normal Descriptor (Write-back Format)

The write-back format of the Transmit Descriptor includes timestamp low, timestamp high, OWN, and Status bits. The write-back format is applicable only for the last descriptor of the corresponding packet. The LD bit (TDES3[28]) is set in the descriptor where the DMA writes back the status and timestamp information for the corresponding Transmit packet.
this format is only applicable to the last descriptor of a packet.

Table 25-9 TDES0 Normal Descriptor (Write-Back Format)

| Bit | Name | Description |
|---|---|---|
| 31:0 | TTSL | Transmit Packet Timestamp Low<br>The DMA updates this field with least significant 32 bits of the timestamp captured for the corresponding Transmit packet. The DMA writes the timestamp only if TTSE bit of TDES2 is set in the first descriptor of the packet. This field has the timestamp only if the Last Segment bit (LS) in the descriptor is set and the Timestamp status (TTSS) bit is set |

Table 25-10 TDES1 Normal Descriptor (Write-Back Format)

Copyright 2022 © Rockchip Electronics Co., Ltd.

| Bit | Name | Description |
|---|---|---|
| 31:0 | TTSH | Transmit Packet Timestamp High<br>The DMA updates this field with the most significant 32 bits of the timestamp captured for corresponding transmit packet. The DMA writes the timestamp only if the TTSE bit of TDES2 is set in the first descriptor of the packet. This field has the timestamp only if the Last Segment bit (LS) in the<br>descriptor is set and Timestamp status (TTSS) bit is set. |

Table 25-11 TDES2 Normal Descriptor (Write-Back Format)

| Bit | Name | Description |
|---|---|---|
| 31:0 | Reserved | Reserved |

Table 25-12 TDES2 Normal Descriptor (Write-Back Format)

| Bit | Name | Description |
|---|---|---|
| 31 | OWN | Own Bit<br>When this bit is set, it indicates that the DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit after it completes the transfer of data given in the associated buffer(s). |
| 30 | CTXT | Context Type<br>This bit should be set to 1'b0 for normal descriptor. |
| 29 | FD | First Descriptor<br>When this bit is set, it indicates that the buffer contains the first segment of a packet. |
| 28 | LD | Last Descriptor<br>When this bit is set, it indicates that the buffer contains the last segment of the packet. When this bit is set, the B1L or B2L field should have a non-zero value. |
| 27:24 | Reserved | Reserved |
| 23 | DE | Descriptor Error<br>When this bit is set, it indicates that the descriptor content is incorrect. The DMA sets this bit during write-back while closing the descriptor. Descriptor Errors can be:<br>■ Incorrect sequence from the context descriptor. For example, a location after the first descriptor for a packet<br>■ All 1s<br>■ CTXT, LD, and FD bits set to 1<br>Note 1: When Descriptor Error occurs due to All 1s or CTXT, LD, and FD bits set to 1, the Transmit DMA closes the transmit descriptor with DE and LD bits set to 1. When IOC bit in TDES2 of corresponding first descriptor is set to 1, Transmit DMA will set the TI bit in the DMA_CH#_Status register.<br>Note 2: Based on CTXT, LD, and FD bits of the transmit descriptor, the subsequent descriptor might be considered as the First Descriptor (even if FD bit is not set) and partial packet is sent. |
| 22:18 | Reserved | Reserved |
| 17 | TTSS | Tx Timestamp Status<br>This status bit indicates that a timestamp has been captured for the corresponding transmit packet. When this bit is set, TDES0 and TDES1 have timestamp values that were captured for the Transmit packet. This field is valid only when the Last Segment control bit (TDES3 [28]) in a<br>descriptor is set. This bit is valid only when IEEE1588 timestamping feature is enabled; otherwise, it is reserved. |
| 16 | EUE | ECC Uncorrectable Error Status<br>Indicates the ECC uncorrectable error in the TSO memory. |

Copyright 2022 © Rockchip Electronics Co., Ltd.

| Bit | Name | Description |
|---|---|---|
| | | Note: Uncorrectable error in Transmit FIFO memory is reported with (Bit 13) FF = 1. This is because, all such packets are flushed by GMAC. |
| 15 | ES | Error Summary<br>This bit indicates the logical OR of the following bits:<br>■ TDES3[0]: IP Header Error<br>■ TDES3[14]: Jabber Timeout<br>■ TDES3[13]: Packet Flush<br>■ TDES3[12]: Payload Checksum Error<br>■ TDES3[11]: Loss of Carrier<br>■ TDES3[10]: No Carrier<br>■ TDES3[9]: Late Collision<br>■ TDES3[8]: Excessive Collision<br>■ TDES3[3]: Excessive Deferral<br>■ TDES3[2]: Underflow Error<br>This bit is also set when EUE (bit 16) is set |
| 14 | JT | Jabber Timeout<br>This bit indicates that the MAC transmitter has experienced a jabber time-out. This bit is set only when the JD bit of the MAC_Configuration register is not set. |
| 13 | PF | Packet Flushed<br>This bit indicates that the DMA or MTL flushed the packet because of a software flush command given by the CPU. |
| 12 | PCE | Payload Checksum Error<br>This bit indicates that the Checksum Offload engine had a failure and did not insert any checksum into the encapsulated TCP, UDP, or ICMP payload. This failure can be either because of insufficient bytes, as indicated by the Payload Length field of the IP Header or the MTL starting to forward the packet to the MAC transmitter in Store-and-Forward mode without the checksum having been calculated yet. This second error condition only occurs when the Transmit FIFO depth is less than the length of the Ethernet packet being transmitted to avoid deadlock, the MTL starts forwarding the packet when the FIFO is full, even in the store-and-forward mode. This error can also occur when Bus Error is detected during packet transfer. When the Full Checksum Offload engine is not enabled, this bit is reserved. |
| 11 | LoC | Loss of Carrier<br>This bit indicates that Loss of Carrier occurred during packet transmission (that is, the gmii_crs_i signal was inactive for one or more transmit clock periods during packet transmission). This is valid only for the packets transmitted without collision and when the MAC operates in the half-duplex mode. |
| 10 | NC | No Carrier<br>This bit indicates that the carrier sense signal form the PHY was not asserted during transmission. |
| 9 | LC | Late Collision<br>This bit indicates that packet transmission was aborted because a collision occurred after the collision window (64 byte times including Preamble in MII mode and 512 byte times including Preamble and Carrier Extension in GMII mode). This bit is not valid if Underflow Error is set. |
| 8 | EC | Excessive Collision<br>This bit indicates that the transmission was aborted after 16 successive collisions while attempting to transmit the current packet. If the DR bit is set in the MAC_Configuration register, this bit is set after first collision and the transmission of the packet is aborted. |
| 7:4 | CC | Collision Count |

Copyright 2022 © Rockchip Electronics Co., Ltd.

| Bit | Name | Description |
|---|---|---|
| | | This 4-bit counter value indicates the number of collisions occurred before the packet was transmitted. The count is not valid when the EC bit is set. |
| 3 | ED | Excessive Deferral<br>This bit indicates that the transmission ended because of excessive deferral of over 24,288 bit times (155,680 bits times in 1000 Mbps mode or Jumbo Packet enabled mode) if DC bit is set in the MAC_Configuration register. When TBS is enabled in full duplex mode and this bit is set, it indicates that the frame has been dropped after the expiry time has reached. |
| 2 | UF | Underflow Error<br>This bit indicates that the MAC aborted the packet because the data arrived late from the system<br>memory. The underflow error can occur because of either of the following conditions:<br>■ The DMA encountered an empty Transmit Buffer while transmitting the packet<br>■ The application filled the MTL Tx FIFO slower than the MAC transmit rate<br>The transmission process enter the suspended state and sets the underflow bit corresponding to a queue in the MTL_Interrupt_Status register. |
| 1 | DB | Deferred Bit<br>This bit indicates that the MAC deferred before transmitting because of presence of carrier. This bit is valid only in the half-duplex mode. |
| 0 | IHE | IP Header Error<br>When IP Header Error is set, this bit indicates that the Checksum Offload engine detected an IP header error. This bit is valid only when Tx Checksum Offload is enabled. Otherwise, it is reserved. If COE detects an IP header error, it still inserts an IPv4 header checksum if the Ethernet Type field indicates an IPv4 payload.<br>In full duplex mode, when EST/Qbv is enabled and this bit is set, it indicates the frame drop status due to Frame Size error or Schedule Error. |

## 25.6.5 Programming Guide

### 25.6.5.1 Initializing DMA

Complete the following steps to initialize the DMA:
1. Provide a software reset. This resets all of the MAC internal registers and logic (bit-0 of DMA_Mode).
2. Wait for the completion of the reset process (poll bit 0 of the DMA_Mode, which is only cleared after the reset operation is completed).
3. Program the following fields to initialize the DMA_SysBus_Mode register:
a. AAL
b. Fixed burst or undefined burst
c. Burst mode values in case of AHB bus interface, OSR_LMT in case of AXI bus interface.
d. If fixed length value is enabled, select the maximum burst length possible on the AXI Bus (bits [7:1])
4. Create a descriptor list for transmit and receive. In addition, ensure that the descriptors are owned by DMA (set bit 31 of descriptor TDES3/RDES3). For more information about descriptors, see section “Descriptors”.
5. Program the Transmit and Receive Ring length registers (DMA_CH(#i)_TxDesc_Ring_Length (for i = 0; i <= GMAC_NUM_DMA_TX_CH-1) and DMA_CH(#i)_RxDesc_Ring_Length (for i = 0; i <= GMAC_NUM_DMA_RX_CH-1)). The ring length programmed must be at least 4.

Copyright 2022 © Rockchip Electronics Co., Ltd. 

6. Initialize receive and transmit descriptor list address with the base address of the transmit and receive descriptor (DMA_CH(#i)_TxDesc_List_Address (for i = 0; i <= GMAC_NUM_DMA_TX_CH-1), DMA_CH(#i)_RxDesc_List_Address (for i = 0; i <= GMAC_NUM_DMA_RX_CH-1)). Also, program transmit and receive tail pointer registers indicating to the DMA about the available descriptors (DMA_CH(#i)_TxDesc_Tail_Pointer (for i = 0; i <= GMAC_NUM_DMA_TX_CH-1) and
DMA_CH(#i)_RxDesc_Tail_Pointer (for i = 0; i <= GMAC_NUM_DMA_RX_CH-1)).
7. Program the settings of the following registers for the parameters like maximum burst-length (PBL) initiated by DMA, descriptor skip lengths, OSP in case of TxDMA, RBSZ in case of RxDMA, and so on:
- DMA_CH(#i)_Control (for i = 0; i <= GMAC_NUM_DMA_TX_CH-1)
- DMA_CH(#i)_TX_Control (for i = 0; i <= GMAC_NUM_DMA_TX_CH-1)
- DMA_CH(#i)_RX_Control (for i = 0; i <= GMAC_NUM_DMA_RX_CH-1)

8. Enable the interrupts by programming the DMA_CH(#i)_Interrupt_Enable (for i = 0; i <= GMAC_NUM_DMA_TX_CH-1) register.
9. Start the Receive and Transmit DMAs by setting SR (bit 0) of the DMA_CH(#i)_RX_Control (for i = 0; i <= GMAC_NUM_DMA_RX_CH-1) and ST (bit 0) of the DMA_CH(#i)_TX_Control (for i = 0; i <= GMAC_NUM_DMA_TX_CH-1) register.
10. Repeat steps 4 to 9 for all the Tx DMA and Rx DMA channels selected in the hardware.

### 25.6.5.2 Initializing MTL Registers

The Transaction Layer (MTL) registers must be initialized to establish the transmit and receive operating modes and commands.
Complete the following steps to initialize the MTL registers:
1. Program the Tx Scheduling (SCHALG) and Receive Arbitration Algorithm (RAA) fields in MTL_Operation_Mode to initialize the MTL operation in case of multiple Tx and Rx queues.
2. Program the Receive Queue to DMA mapping in MTL_RxQ_DMA_Map0 and MTL_RxQ_DMA_Map1 registers.
3. Program the following fields to initialize the mode of operation in the MTL_TxQ0_Operation_Mode register.
a. Transmit Store And Forward (TSF) or Transmit Threshold Control (TTC) in case of threshold mode
b. Transmit Queue Enable (TXQEN) to value 2'b10 to enable Transmit Queue0
c. Transmit Queue Size (TQS)
4. Program the following fields to initialize the mode of operation in the MTL_RxQ0_Operation_Mode register:
a. Receive Store and Forward (RSF) or RTC in case of Threshold mode
b. Flow Control Activation and De-activation thresholds for MTL Receive FIFO (RFA and RFD)
c. Error Packet and undersized good Packet forwarding enable (FEP and FUP)
d. Receive Queue Size (RQS)
5. Repeat previous two steps for all MTL Tx and Rx queues selected in the configuration.

### 25.6.5.3 Initializing MAC

The MAC configuration registers establish the operating mode of the MAC. These registers must be initialized before initializing the DMA.
The following MAC Initialization operations can be performed after DMA initialization. If the MAC initialization is completed before the DMA is configured, enable the MAC receiver (last step in the following sequence) only after the DMA is active. Otherwise, received frames fill the Rx FIFO and overflow.
1. Provide the MAC address registers: MAC_Address0_High and MAC_Address0_Low. If more than one MAC address is enabled in your configuration, program the MAC addresses appropriately.
2. Program the following fields to set the appropriate filters for the incoming frames in the MAC_Packet_Filter register:
a. Receive All
b. Promiscuous mode
c. Hash or Perfect Filter

Copyright 2022 © Rockchip Electronics Co., Ltd. 

d. Unicast, multicast, broadcast, and control frames filter settings
3. Program the following fields for proper flow control in the MAC_Q0_Tx_Flow_Ctrl register:
a. Pause time and other Pause frame control bits
b. Transmit Flow control bits
c. Flow Control Busy
4. Program the MAC_Interrupt_Enable register, as required, and if applicable, for your configuration.
5. Program the appropriate fields in the MAC_Configuration register. For ex: Inter-packet gap while transmission and jabber disable.
6. Set bit 0 and 1 in MAC_Configuration registers to start the MAC transmitter and receiver.

#### 25.6.5.4 Performing Normal Receive and Transmit Operation

During normal operation of the GMAC, normal and transmit interrupts are read, descriptors polled, the DMA is suspended (if it does not own descriptors), and values of current host transmitter or receiver descriptor pointers are read for debugging.
For normal operation, complete the following steps:
1. For normal transmit and receive interrupts, read the interrupt status. Then, poll the descriptors, reading the status of the descriptor owned by the Host (either transmit or receive).
2. Set appropriate values for the descriptors, ensuring that transmit and receive descriptors are owned by the DMA to resume the transmission and reception of data.
3. If the descriptors are not owned by the DMA (or no descriptor is available), the DMA goes into SUSPEND state. The transmission or reception can be resumed by freeing the descriptors and writing the descriptor tail pointer to Tx/Rx tail pointer register (DMA_CH[n]_TxDesc_Tail_Pointer and DMA_CH[n]_RxDesc_Tail_Pointer).
4. The values of the current host transmitter or receiver descriptor address pointer can be read for the debug process (DMA_CH[n]_Current_App_TxDesc and DMA_CH[n]_Current_App_RxDesc).
5. The values of the current host transmit buffer address pointer and receive buffer address pointer can be read for the debug process (Register DMA_CH[n]_Current_App_TxBuffer and DMA_CH[n]_Current_App_RxBuffer)

#### 25.6.5.5 Stopping and Starting Transmission

Complete the following steps to pause the transmission for some time.
1. Disable the Transmit DMA (if applicable) by clearing Bit 0 (ST) of DMA_CH(#i)_TX_Control (for i = 0; i <= GMAC_NUM_DMA_TX_CH-1) Register.
2. Wait for any previous frame transmissions to complete. You can check this by reading the appropriate bits of MTL_TxQ0_Debug Register (TRCSTS is not 01 and TXQSTS=0).
3. Disable the MAC transmitter and MAC receiver by clearing Bit (RE) and Bit 1(TE) of the MAC_Configuration Register.
4. Disable the Receive DMA (if applicable), after making sure that the data in the Rx FIFO is transferred to the system memory (by reading the appropriate bits of MTL_TxQ0_Debug Register, PRXQ=0 and RXQSTS=00).
5. Make sure that both Tx Queue and Rx Queue are empty (TXQSTS is 0 in MTL_TxQ0_Debug Register and RXQSTS is 0 in MTL_RxQ0_Debug Register).
6. To restart the operation, first start the DMAs, and then enable the MAC Transmitter and Receiver.

#### 25.6.5.6 Initialization Guidelines for System Time Generation

You can enable the timestamp feature by setting Bit 0 of the MAC_Timestamp_Control Register. However, it is essential that the timestamp counter be initialized after this bit is set. Complete the following steps during GMAC initialization:
1. Mask the Timestamp Trigger interrupt by clearing the bit 16 of MAC_Interrupt_Enable Register.
2. Set Bit 0 of MAC_Timestamp_Control Register to enable timestamping.
3. Program MAC_Sub_Second_Increment Register based on the PTP clock frequency.

*Copyright 2022 © Rockchip Electronics Co., Ltd.* 

4. If you are using the Fine Correction approach, program MAC_Timestamp_Addend and set Bit 5 of MAC_Timestamp_Control Register.
5. Poll the MAC_Timestamp_Control Register until Bit 5 is cleared.
6. Program Bit 1 of MAC_Timestamp_Control Register to select the Fine Update method (if required).
7. Program MAC_System_Time_Seconds_Update Register and MAC_System_Time_Nanoseconds_Update Register with the appropriate time value.
8. Set Bit 2 in MAC_Timestamp_Control Register.
The timestamp counter starts operation as soon as it is initialized with the value written in the Timestamp Update registers. If one-step timestamping is enabled
a. To enable one-step timestamping, program Bit 27 of the TDES3 Context Descriptor.
b. Program registers MAC_Timestamp_Ingress_Asym_Corr and MAC_Timestamp_Egress_Asym_Corr to update the correction field in PDelay_Req PTP messages.
9. Enable the MAC receiver and transmitter for proper timestamping.

#### 25.6.5.7 Coarse Correction Method

To synchronize or update the system time in one process (coarse correction method), complete the following steps:
1. Set the offset (positive or negative) in the Timestamp Update registers (MAC_System_Time_Seconds_Update and MAC_System_Time_Nanoseconds_Update).
2. Set Bit 3 (TSUPDT) of MAC_Timestamp_Control Register. The value in the Timestamp Update registers is added to or subtracted from the system time when the TSUPDT bit is cleared.

#### 25.6.5.8 Programming Guidelines for TSO

The TCP Segmentation Offload (TSO) engine is used to offload the TCP segmentation functions to the hardware. To program the TSO, set the TSE bit to enable TCP packet segmentation, and program descriptor fields to enable TSO for the current packet.
Complete the following steps to program TSO:
1. Program the TSE bit of corresponding DMA_CH[n]_Tx_Control register to enable TCP packet segmentation in that DMA.
2. In addition to the normal transfer descriptor setting, the following descriptor fields must be programmed to enable TSO for the current packet:
a. Enable TSE in Bit 18 of TDES3
b. Program the length of the un-segmented TCP/IP packet payload in bits [17:0] of TDES3 and the TCP header in bits [22:19] of TDES3.
c. Program the maximum size of the segment in MSS of DMA_CH[n]_Control register or MSS in the context descriptor. If MSS field is programmed in both DMA_CH[n]_Control register and in the context descriptor, the latest software programmed sequence is considered.
3. The header of the unsegmented TCP/IP packet should be in Buffer 1 of the first descriptor and this buffer must not hold any payload bytes. The payload is allocated to Buffer 2 and the buffers of the subsequent descriptors.

#### 25.6.5.9 Programming Guidelines for Multi-Channel Multi-Queuing Transmit

1. Program the Transmit queue size in the TQS field of MTL_TxQ[n]_Operation_Mode register. Based on the value programmed in the TQS field, the size of the queue is determined.
In the Transmit operation, the number of channels is equal to the number of the queues. Due to this reason, the Channel-to-Queue mapping is fixed.
2. For a queue to be used, the queue needs to be enabled in TXQEN in the corresponding MTL_TxQ[n]_Operation_Mode Register. In DMA configurations, the ST bit of DMA_CH[n]_Tx_Control Register and corresponding TXQEN in MTL_TxQ[n]_Operation Mode Register needs to be enabled.
3. The scheduling method needs to be programmed in SCHALG of MTL_Operation_Mode register.

Copyright 2022 © Rockchip Electronics Co., Ltd. 

4. Program the MTL_TxQ[n]_Quantum_Weight for DCB queue as per the selected algorithm. In case of CBS algorithm in AVB queues, the MTL_TxQ[n]_ETS_Control, MTL_TxQ[n]_SendSlopeCredit, MTL_TxQ[n]_HiCredit and MTL_TxQ[n]_LoCredit registers also need to be programmed as required.
5. If DCB is enabled and PFC function is required, program MAC_TxQ_Prty_Map0 Register to assign a fixed priority to the queue. This priority assigned is used for determining if the corresponding queue should stop transmitting packet based on the received PFC packet.

**Receive**
1. Program the Receive queue size in the RQS field of MTL_RxQ[n]_Operation_Mode Register. Based on the value programmed in RQS field, the size of the queue is determined.
2. Enable the Receive Queues 0 to 7 in the fields RXQ0EN to RXQ7EN in MAC_RxQ_Ctrl0 Register for AV or DCB. In DMA configurations, SR bit of statically or dynamically mapped DMA_CH[n]_Rx_Control Register and corresponding RXQ[n]_EN in MAC_RxQ_Ctrl0 Register needs to be enabled.
3. The MAC routes the Rx packets to the Rx Queues based on following packet types:
   a. AV PTP Packets: Based on the programming of AVPTPQ in MAC_RxQ_Ctrl1 Register.
   b. AV Untagged Control packets: Based on the programming of AVCPQ in MAC_RxQ_Ctrl1 Register.
   c. Data Center Bridging (DCB) related Link Layer Discovery Protocol (LLDP) packets. Program
   DCBCPQ in MAC_RxQ_Ctrl1 Register to indicate to MAC which queue should get the DCB packets.
   d. VLAN Tag Priority field in VLAN Tagged packets: Program PSRQ7-0 of the MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 Register for the routing of tagged packets based on the USP (user Priority) field of the received packets to the Rx Queues 0 to 7.
   e. The AV tagged control and data packets are also routed based on PSRQ field of the MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers.
4. If multiple RX DMA channels are enabled, the following programming should be done for proper arbitration and mapping:
   a. Program the RAA field of MTL_Operation_Mode register to select the arbitration algorithm to decide which RxQ is read out from the RxFIFO memory.
   b. Program the MTL_RxQ[n]_Control to decide the weights and the packet arbitration for each RxQ.
   c. If static mapping is programmed in MTL_RxQ_DMA_Map[n] register (RXQ[n]DADMACH is reset to 0), bits RXQx2DMA and others need to be programmed to select the channel for which each queue is mapped.
   d. Set RXQ[n]DADMACH bit in MTL_RxQ_DMA_Map0 Register to select dynamic mapping of
   packets in each RxQueue.
   e. In dynamic channel mapping, the routing of a packet to a specific RxDMA channel is decided by the value of DCS field in the lowest MAC Address Register.

## 25.6.6 Transmit Context Descriptor

The context descriptor is used to provide the timestamps for one-step timestamp correction, VLAN Tag ID for VLAN insertion feature. The Transmit Context descriptor can be provided any time before a packet descriptor. The context is valid for the current packet and subsequent packets. The context descriptor is used to provide the timestamps for one-step timestamp correction and VLAN Tag ID for VLAN insertion feature. Write back is done on a context descriptor only to reset the OWN bit.

*Copyright 2022 © Rockchip Electronics Co., Ltd.* 

Table 25-13 TDES0 Context Descriptor

| Bit | Name | Description |
|---|---|---|
| 31:0 | TTSL | Transmit Packet Timestamp Low<br>For one-step correction, the driver can provide the lower 32 bits of timestamp in this descriptor word.<br>The DMA uses this value as the low word for doing one-step timestamp correction. This field is valid only if the OSTC and TCMSSV bits of TDES3 context descriptor are set. |

Table 25-14 TDES1 Context Descriptor

| Bit | Name | Description |
|---|---|---|
| 31:0 | TTSH | Transmit Packet Timestamp High<br>For one-step correction, the driver can provide the upper 32 bits of timestamp in this descriptor. The DMA uses this value as the high word for doing one-step timestamp correction. This field is valid only if the OSTC and TCMSSV bits of TDES3 context descriptor are set. |

Table 25-15 TDES2 Context Descriptor

| Bit | Name | Description |
|---|---|---|
| 31:16 | IVT | Inner VLAN Tag<br>When the IVLTV bit of TDES3 context descriptor is set and the TCMSSV and OSTC bits of TDES3 context descriptor are reset, TDES2[31:16] contains the inner VLAN Tag to be inserted in the subsequent Transmit packets. |
| 15:14 | Reserved | Reserved |
| 13:0 | MSS | Maximum Segment Size<br>When the Enable TCP Segmentation Offloading for TCP/IP Packets option is selected, the driver can provide maximum segment size in this field. This segment size is used while segmenting the TCP/IP payload. This field is valid only if the TCMSSV bit of TDES3 context descriptor is set and the OSTC bit of the TDES3 context descriptor is reset. |

Table 25-16 TDES3 Context Descriptor

| Bit | Name | Description |
|---|---|---|
| 31 | OWN | Own Bit<br>When this bit is set, it indicates that the GMAC DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit immediately after the read. |
| 30 | CTXT | Context Type<br>This bit should be set to 1'b1 for Context descriptor. |
| 29:28 | Reserved | Reserved |
| 27 | OSTC | One-Step Timestamp Correction Enable<br>When this bit is set, the DMA performs a one-step timestamp correction with reference to the timestamp values provided in TDES0 and TDES1. |
| 26 | TCMSSV | One-Step Timestamp Correction Input or MSS Valid<br>When this bit and the OSTC bit are set, it indicates that the Timestamp Correction input provided in TDES0 and TDES1 is valid.<br>When the OSTC bit is reset and this bit and the TSE bit of TDES3 are set in subsequent normal descriptor, it indicates that the MSS input in TDES2 is valid. |
| 25:24 | Reserved | Reserved |

Copyright 2022 © Rockchip Electronics Co., Ltd.

| Bit | Name | Description |
|---|---|---|
| 23 | DE | Descriptor Error<br>When this bit is set, it indicates that the descriptor content is incorrect.The DMA sets this bit during write-back while closing the context descriptor.<br>Descriptor Errors can be:<br>■ Incorrect sequence from the context descriptor. For example, a location before the first descriptor for a packet<br>■ All 1s<br>■ CD, LD, and FD bits set to 1<br>Note 1: When Descriptor Error occurs due to All 1s or CTXT, LD, and FD bits set to 1, the Transmit DMA closes the transmit descriptor with DE and LD bits set to 1. When IOC bit in TDES2 of corresponding first descriptor is set to 1, Transmit DMA will set the TI bit in the DMA_CH#_Status<br>Register.<br>Note 2: Based on CTXT, LD, and FD bits of the transmit descriptor, the subsequent descriptor might be considered as the First Descriptor (even if FD bit is not set) and partial packet is sent. |
| 22:20 | Reserved | Reserved |
| 19:18 | IVTIR | Inner VLAN Tag Insert or Replace<br>When this bit is set, these bits request the MAC to perform Inner VLAN tagging or un-tagging before transmitting the packets. If the packet is modified for VLAN tags, the MAC automatically recalculates and replaces the CRC bytes.<br>The following list describes the values of these bits:<br>■ 2'b00: Do not add the inner VLAN tag.<br>■ 2'b01: Remove the inner VLAN tag from the packets before transmission. This option should be used only with the VLAN frames.<br>■ 2'b10: Insert an inner VLAN tag with the tag value programmed in the MAC_Inner_VLAN_Incl register or context descriptor.<br>■ 2'b11: Replace the inner VLAN tag in packets with the tag value programmed in the MAC_Inner_VLAN_Incl register or context descriptor. This option should be used only with the VLAN frames.<br>These bits are valid when the Enable SA and VLAN Insertion on Tx and Enable Double VLAN Processing options are selected. |
| 17 | IVLTV | Inner VLAN Tag Valid<br>When this bit is set, it indicates that the IVT field of TDES2 is valid. |
| 16 | VLTV | VLAN Tag Valid<br>When this bit is set, it indicates that the VT field of TDES3 is valid. |
| 15:0 | VT | VLAN Tag<br>This field contains the VLAN Tag to be inserted or replaced in the packet. This field is used as VLAN Tag only when the VLTI bit of the MAC_VLAN_Incl register is reset. |

### 25.6.7 Receive Descriptors

The DMA in GMAC attempts to read a descriptor only if the Tail Pointer is different from the Base Pointer or current pointer. It is recommended to have a descriptor ring with a length that can accommodate at least two complete packets received by the MAC. Otherwise, the performance of the DMA is impacted greatly because of the unavailability of the descriptors. In such situations, the RxFIFO in MTL becomes full and starts dropping packets.

The following Receive Descriptors are present:

- Normal descriptors
- Context descriptors

All RX descriptors are prepared by the software and given to the DMA as “Normal” Descriptors with the content as shown in Receive Normal Descriptor (Read Format). The DMA reads this descriptor and after transferring a received packet (or part of) to the buffers indicated by the descriptor, the Rx DMA will close the descriptor with the corresponding

Copyright 2022 © Rockchip Electronics Co., Ltd.

packet status. The format of this status is given in the "Receive Normal Descriptor (Write-Back Format)". For some packets, the normal descriptor bits are not enough to write the complete status. For such packets, the RX DMA writes the extended status to the next descriptor (without processing or using the Buffers/ Pointers embedded in that descriptor). The format and content of the descriptor write back is described in "Receive Context Descriptor".

## 25.6.8 Receive Normal Descriptors(Read Format)

Table 25-17 TDES0 Normal Descriptor(Read Format)

| Bit | Name | Description |
|---|---|---|
| 31:0 | BUF1AP | Header or Buffer 1 Address Pointer<br>When the SPH bit of Control register of a channel is reset, these bits indicate the physical address of Buffer 1. When the SPH bit is set, these bits indicate the physical address of Header Buffer where the Rx DMA writes the L2/L3/L4 header bytes of the received packet.<br>The application can program a byte-aligned address for this buffer which means that the LS bits of this field can be non-zero. However, while transferring the start of packet, the DMA performs a Write operation with RDES0[1:0] (or RDES0[2:0]/[3:0] in case of 64-/128-bit configuration) as zero. However, the packet data is shifted as per actual offset as given by buffer address pointer.<br>If the address pointer points to a buffer where the middle or last part of the packet is stored, the DMA ignores the offset address and writes to the full location as indicated by the data-width. |

Table 25-18 TDES1 Normal Descriptor(Read Format)

| Bit | Name | Description |
|---|---|---|
| 31:0 | Reserved or BUF1AP | In 64-bit addressing mode, this field contains the most-significant 32 bits of the Buffer 1 Address Pointer. Otherwise, this field is reserved. |

Table 25-19 TDES2 Normal Descriptor(Read Format)

| Bit | Name | Description |
|---|---|---|
| 31:0 | Reserved or BUF1AP | In 64-bit addressing mode, this field contains the most-significant 32 bits of the Buffer 1 Address Pointer. Otherwise, this field is reserved. |

Table 25-20 TDES3 Normal Descriptor(Read Format)

| Bit | Name | Description |
|---|---|---|
| 31 | OWN | Own Bit<br>When this bit is set, it indicates that the GMAC DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit when either of the following conditions is true:<br>■ The DMA completes the packet reception<br>■ The buffers associated with the descriptor are full |
| 30 | IOC | Interrupt Enabled on Completion<br>When this bit is set, an interrupt is issued to the application when the DMA closes this descriptor. |
| 29:26 | Reserved | Reserved |
| 25 | BUF2V | Buffer 2 Address Valid<br>When this bit is set, it indicates to the DMA that the buffer 2 address specified in RDES2 is valid. |

Copyright 2022 © Rockchip Electronics Co., Ltd.

| Bit | Name | Description |
|---|---|---|
| | | The application must set this bit so that the DMA can use the address, to which the Buffer 2 address in RDES2 is pointing, to write received packet data. |
| 24 | BUF1V | Buffer 1 Address Valid<br>When set, this indicates to the DMA that the buffer 1 address specified in RDES1 is valid.<br>The application must set this value if the address pointed to by Buffer 1 address in RDES1 can be used by the DMA to write received packet data. |
| 23:0 | Reserved | Reserved |

### 25.6.9 Receive Normal Descriptors(Write-Back Format)

Table 25-21 TDES0 Normal Descriptor(Write-Back Format)

| Bit | Name | Description |
|---|---|---|
| 31:16 | IVT | Inner VLAN Tag<br>This field contains the Inner VLAN tag of the received packet if the RS0V bit of RDES3 is set.<br>This is valid only when Double VLAN tag processing and VLAN tag stripping are enabled. |
| 15:0 | OVT | Outer VLAN Tag<br>This field contains the Outer VLAN tag of the received packet if the RS0V bit of RDES3 is set. |

Table 25-22 TDES1 Normal Descriptor(Write-Back Format)

| Bit | Name | Description |
|---|---|---|
| 31:16 | OPC | OAM Sub-Type Code, or MAC Control Packet opcode<br>OAM Sub-Type Code<br>If Bits[18:16] of RDES3 are set to 3'b111, this field contains the OAM sub-type and code fields.<br>MAC Control Packet opcode<br>If Bits[18:16] of RDES3 are set to 3'b110, this field contains the MAC Control packet opcode field. |
| 15 | TD | Timestamp Dropped<br>This bit indicates that the timestamp was captured for this packet but it got dropped in the MTL Rx FIFO because of overflow.<br>This bit is available only when you select the Timestamp feature. Otherwise, this bit is reserved. |
| 14 | TSA | Timestamp Available<br>When Timestamp is present, this bit indicates that the timestamp value is available in a context descriptor word 2 (RDES2) and word 1(RDES1).<br>This is valid only when the Last Descriptor bit (RDES3 [28]) is set.<br>The context descriptor is written in the next descriptor just after the last normal descriptor for a packet. |
| 13 | PV | PTP Version<br>This bit indicates that the received PTP message has the IEEE 1588 version 2 format. When this bit is reset, it indicates the IEEE 1588 version 1 format.<br>This bit is available only when you select the Timestamp feature. Otherwise, this bit is reserved. |
| 12 | PFT | PTP Packet Type<br>This bit indicates that the PTP message is sent directly over Ethernet.<br>This bit is available only when you select the Timestamp feature. Otherwise, this bit is reserved. |
| 11:8 | PMT | PTP Message Type<br>These bits are encoded to give the type of the message received:<br>■ 0000: No PTP message received |

| Bit | Name | Description |
|---|---|---|
| | | ■ 0001: SYNC (all clock types)<br>■ 0010: Follow_Up (all clock types)<br>■ 0011: Delay_Req (all clock types)<br>■ 0100: Delay_Resp (all clock types)<br>■ 0101: Pdelay_Req (in peer-to-peer transparent clock)<br>■ 0110: Pdelay_Resp (in peer-to-peer transparent clock)<br>■ 0111: Pdelay_Resp_Follow_Up (in peer-to-peer transparent clock)<br>■ 1000: Announce<br>■ 1001: Management<br>■ 1010: Signaling<br>■ 1011–1110: Reserved<br>■ 1111: PTP packet with Reserved message type<br>These bits are available only when you select the Timestamp feature. |
| 7 | IPCE | IP Payload Error<br>When this bit is set, it indicates either of the following:<br>■ The 16-bit IP payload checksum (that is, the TCP, UDP, or ICMP checksum) calculated by the MAC does not match the corresponding checksum field in the received segment.<br>■ The TCP, UDP, or ICMP segment length does not match the payload length value in the IP Header field.<br>■ The TCP, UDP, or ICMP segment length is less than minimum allowed segment length for TCP, UDP, or ICMP.<br>Bit 15 (ES) of RDES3 is not set when this bit is set. |
| 6 | IPCB | IP Checksum Bypassed<br>This bit indicates that the checksum offload engine is bypassed. This bit is available when you select the Enable Receive TCP/IP Checksum Check feature. |
| 5 | IPV6 | IPv6 header Present<br>This bit indicates that an IPV6 header is detected. When the Enable Split Header Feature option is selected and the SPH bit of Control Register of a channel is set, the IPV6 header is available in the header buffer area to which RDES0 is pointing. |
| 4 | IPV4 | IPV4 Header Present<br>This bit indicates that an IPV4 header is detected. When the SPH bit of RDES3 is set, the IPV4 header is available in the header buffer area to which RDES0 is pointing. |
| 3 | IPHE | IP Header Error<br>When this bit is set, it indicates either of the following:<br>■ The 16-bit IPv4 header checksum calculated by the MAC does not match the received checksum bytes.<br>■ The IP datagram version is not consistent with the Ethernet Type value.<br>■ Ethernet packet does not have the expected number of IP header bytes.<br>This bit is valid when either Bit 5 or Bit 4 is set. This bit is available when you select the Enable Receive TCP/IP Checksum Check feature. |
| 2:0 | PT | Payload Type<br>These bits indicate the type of payload encapsulated in the IP datagram processed by the Receive Checksum Offload Engine (COE):<br>■ 3'b000: Unknown type or IP/AV payload not processed<br>■ 3'b001: UDP<br>■ 3'b010: TCP<br>■ 3'b011: ICMP<br>■ 3'b110: AV Tagged Data Packet<br>■ 3'b111: AV Tagged Control Packet<br>■ 3'b101: AV Untagged Control Packet |

| Bit | Name | Description |
|---|---|---|
| | | ■ 3'b100: IGMP if IPV4 Header Present bit is set else DCB (LLDP) Control Packet<br>If the COE does not process the payload of an IP datagram because there is an IP header error or fragmented IP, it sets these bits to 3'b000. |

Table 25-23 TDES2 Normal Descriptor(Write-Back Format)

| Bit | Name | Description |
|---|---|---|
| 31:29 | L3L4FM | Layer 3 and Layer 4 Filter Number Matched<br>These bits indicate the number of the Layer 3 and Layer 4 Filter that matched the received packet:<br>■ 000: Filter 0<br>■ 001: Filter 1<br>■ 010: Filter 2<br>■ 011: Filter 3<br>■ 100: Filter 4<br>■ 101: Filter 5<br>■ 110: Filter 6<br>■ 111: Filter 7<br>This field is valid only when Bit 28 or Bit 27 is set high. When more than one filter matches, these bits give the number of lowest filter.<br>Note: This status is not available when Flexible RX Parser is enabled. |
| 28 | L4FM | Layer 4 Filter Match<br>When this bit is set, it indicates that the received packet matches one of the enabled Layer 4 Port Number fields. This status is given only when one of the following conditions is true:<br>■ Layer 3 fields are not enabled and all enabled Layer 4 fields match<br>■ All enabled Layer 3 and Layer 4 filter fields match<br>When more than one filter matches, this bit gives the layer 4 filter status of filter indicated by Bits[31:29].<br>Note: This status is not available when Flexible RX Parser is enabled. |
| 27 | L3FM | Layer 3 Filter Match<br>When this bit is set, it indicates that the received packet matches one of the enabled Layer 3 IP Address fields. This status is given only when one of the following conditions is true:<br>■ All enabled Layer 3 fields match and all enabled Layer 4 fields are bypassed<br>■ All enabled filter fields match<br>When more than one filter matches, this bit gives the layer 3 filter status of filter indicated by Bits[31:29].<br>Note: This status is not available when Flexible RX Parser is enabled. |
| 26:19 | MADRM | MAC Address Match or Hash Value<br>When the HF bit is reset, this field contains the MAC address register number that matched the Destination address of the received packet. This field is valid only if the DAF bit is reset.<br>When the HF bit is set, this field contains the hash value computed by the MAC. A packet passes the hash filter when the bit corresponding to the hash value is set in the hash filter register.<br>Note: This status is not available when Flexible RX Parser is enabled. |
| 18 | HF | Hash Filter Status<br>When this bit is set, it indicates that the packet passed the MAC address hash filter. Bits[26:19] indicate the hash value.<br>Note: This status is not available when Flexible RX Parser is enabled. |
| 17 | DAF/RXPI | Destination Address Filter Fail<br>When Flexible RX Parser is disabled, and this bit is set, it indicates that the packet failed the DA Filter in the MAC. |

Copyright 2022 © Rockchip Electronics Co., Ltd.

| Bit | Name | Description |
|---|---|---|
| | | When Flexible RX Parser is enabled, this bit is set to indicate that the packet parsing is incomplete (RXPI) due to ECC error.<br>Note: When this bit is set, ES bit of RDES3 is also set. |
| 16 | SAF/RXPD | SA Address Filter Fail<br>When Flexible RX Parser is disabled, and this bit is set, it indicates that the packet failed the SA Filter in the MAC.<br>When Flexible RX Parser is enabled, this bit is set to indicate that the packet is dropped (RXPD) by the parser.<br>Note: When this bit is set, ES bit of RDES3 is also set. |
| 15 | OTS | VLAN Filter Status<br>When set, this bit indicates that the VLAN Tag of the received packed passed the VLAN filter.<br>This bit is valid only when GMAC_ERVFE is not enabled.<br>If GMAC_ERVFE is enabled, the bit is redefined as Outer VLAN Tag Filter Status (OTS).<br>This bit is valid for both Single and Double VLAN Tagged frames. |
| 14 | ITS | Inner VLAN Tag Filter Status (ITS)<br>This bit is valid only when GMAC_ERVFE is enabled.<br>This bit is valid only for Double VLAN Tagged frames, when Double VLAN Processing is enabled.<br>For more information, see the Filter Status topic. |
| 13:11 | Reserved | Reserved |
| 10 | ARPNR | ARP Reply Not Generated<br>When this bit is set, it indicates that the MAC did not generate the ARP Reply for received ARP Request packet. This bit is set when the MAC is busy transmitting ARP reply to earlier ARP request (only one ARP request is processed at a time).<br>This bit is reserved when the Enable IPv4 ARP Offload option is not selected. |
| 9:0 | HL | L3/L4 Header Length<br>This field contains the length of the header of the packet split by the MAC at L3 or L4 header.<br>boundary as identified by the MAC receiver. This field is valid only when the first descriptor bit is set (FD = 1).<br>The header data is written to the Buffer 1 address of corresponding descriptor. If header length is zero, this field is not valid. It implies that the MAC did not identify and split the header.<br>This field is valid when the Enable Split Header Feature option is selected. |

Table 25-24 TDES3 Normal Descriptor(Write-Back Format)

| Bit | Name | Description |
|---|---|---|
| 31 | OWN | Own Bit<br>When this bit is set, it indicates that the GMAC DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit when either of the following conditions is true:<br>■ The DMA completes the packet reception<br>■ The buffers associated with the descriptor are full |
| 30 | CTXT | Receive Context Descriptor<br>When this bit is set, it indicates that the current descriptor is a context type descriptor. The DMA writes 1'b0 to this bit for normal receive descriptor.<br>When CTXT and FD bits are used together, {CTXT, FD}<br>■ 2’b00: Intermediate Descriptor<br>■ 2’b01: First Descriptor<br>■ 2’b10: Reserved |

| Bit | Name | Description |
|---|---|---|
| | | ■ 2'b11: Descriptor Error (due to all 1s)<br>Note: When Descriptor Error occurs, the Receive DMA closes the receive descriptor indicating Descriptor Error. This receive descriptor is skipped and the buffer addresses are not used to write the packet data Receive DMA will set the CDE bit in DMA_CH#_Status register but not the RI bit even when IOC is set, as this is not marked as last receive descriptor for the packet. The subsequent valid receive descriptor is used to write the packet data. |
| 29 | FD | First Descriptor<br>When this bit is set, it indicates that this descriptor contains the first buffer of the packet. If the size of the first buffer is 0, the second buffer contains the beginning of the packet. If the size of the second buffer is also 0, the next descriptor contains the beginning of the packet.<br>See the CTXT bit description for details of using the CTXT bit and FD bit together. |
| 28 | LD | Last Descriptor<br>When this bit is set, it indicates that the buffers to which this descriptor is pointing are the last buffers of the packet. |
| 27 | RS2V | Receive Status RDES2 Valid<br>When this bit is set, it indicates that the status in RDES2 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set. |
| 26 | RS1V | Receive Status RDES1 Valid<br>When this bit is set, it indicates that the status in RDES1 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set. |
| 25 | RS0V | Receive Status RDES0 Valid<br>When this bit is set, it indicates that the status in RDES0 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set. |
| 24 | CE | CRC Error<br>When this bit is set, it indicates that a Cyclic Redundancy Check (CRC) Error occurred on the received packet. This field is valid only when the LD bit of RDES3 is set. |
| 23 | GP | Giant Packet<br>When this bit is set, it indicates that the packet length exceeds the specified maximum Ethernet size of 1518, 1522, or 2000 bytes (9018 or 9022 bytes if jumbo packet enable is set).<br>Note: Giant packet indicates only the packet length. It does not cause any packet truncation. |
| 22 | RWT | Receive Watchdog Timeout<br>When this bit is set, it indicates that the Receive Watchdog Timer has expired while receiving the current packet. The current packet is truncated after watchdog timeout. |
| 21 | OE | Overflow Error<br>When this bit is set, it indicates that the received packet is damaged because of buffer overflow in Rx FIFO.<br>Note: This bit is set only when the DMA transfers a partial packet to the application. This happens only when the Rx FIFO is operating in the threshold mode. In the store-and-forward mode, all partial packets are dropped completely in Rx FIFO. |
| 20 | RE | Receive Error<br>When this bit is set, it indicates that the gmii_rxer_i signal is asserted while the gmii_rxdv_i signal is asserted during packet reception. This error also includes carrier extension error in the GMII and half-duplex |

| Bit | Name | Description |
|---|---|---|
| | | mode. Error can be of less or no extension, or error (rxd!= 0f) during extension. |
| 19 | DE | Dribble Bit Error<br>When this bit is set, it indicates that the received packet has a non-integer multiple of bytes (odd nibbles). This bit is valid only in the MII Mode. |
| 18:16 | LT | Length/Type Field<br>This field indicates if the packet received is a length packet or a type packet. The encoding of the 3<br>bits is as follows:<br>■ 3'b000: The packet is a length packet<br>■ 3'b001: The packet is a type packet.<br>■ 3'b011: The packet is a ARP Request packet type<br>■ 3'b100: The packet is a type packet with VLAN Tag<br>■ 3'b101: The packet is a type packet with Double VLAN Tag<br>■ 3'b110: The packet is a MAC Control packet type<br>■ 3'b111: The packet is a OAM packet type<br>■ 3'b010: Reserved |
| 15 | ES | Error Summary<br>When this bit is set, it indicates the logical OR of the following bits:<br>■ RDES3[24]: CRC Error<br>■ RDES3[19]: Dribble Error<br>■ RDES3[20]: Receive Error<br>■ RDES3[22]: Watchdog Timeout<br>■ RDES3[21]: Overflow Error<br>■ RDES3[23]: Giant Packet<br>■ RDES2[17]: Destination Address Filter Fail, when Flexible RX Parser is enabled<br>■ RDES2[16]: SA Address Filter Fail, when Flexible RX Parser is enabled<br>This field is valid only when the LD bit of RDES3 is set. |
| 14 | PL | Packet Length<br>These bits indicate the byte length of the received packet that was transferred to system memory (including CRC).<br>This field is valid when the LD bit of RDES3 is set and Overflow Error bits are reset. The packet length also includes the two bytes appended to the Ethernet packet when IP checksum calculation is enabled and the received packet is not a MAC control packet.<br>This field is valid when the LD bit of RDES3 is set. When the Last Descriptor and Error Summary bits are not set, this field indicates the accumulated number of bytes that have been transferred for the current packet. |

### 25.6.10 Receive Context Descriptor

This descriptor is read-only for the application. Only the DMA can write to this descriptor. The context descriptor provides information about the extended status related to the last received packet. The Bit 30 of RDES3 indicates the context type descriptor.

Table 25-25 TDES0 Context Descriptor

| Bit | Name | Description |
|---|---|---|
| 31:0 | RSTL | Receive Packet Timestamp Low<br>The DMA updates this field with least significant 32 bits of the timestamp captured for corresponding Receive packet. When this field and the RTSH field of RDES1 show all-ones value, the timestamp must be considered as corrupt. |

Table 25-26 TDES1 Context Descriptor

## 25.6.11 Clock Architecture

In RMII mode, reference clock and TX/RX clock can be from CRU or external OSC as following figure. The mux selecting rmii_speed is PHP_GRF_CLK_CON1[2]/PHP_GRF_CLK_CON1[7].

Copyright 2022 © Rockchip Electronics Co., Ltd.

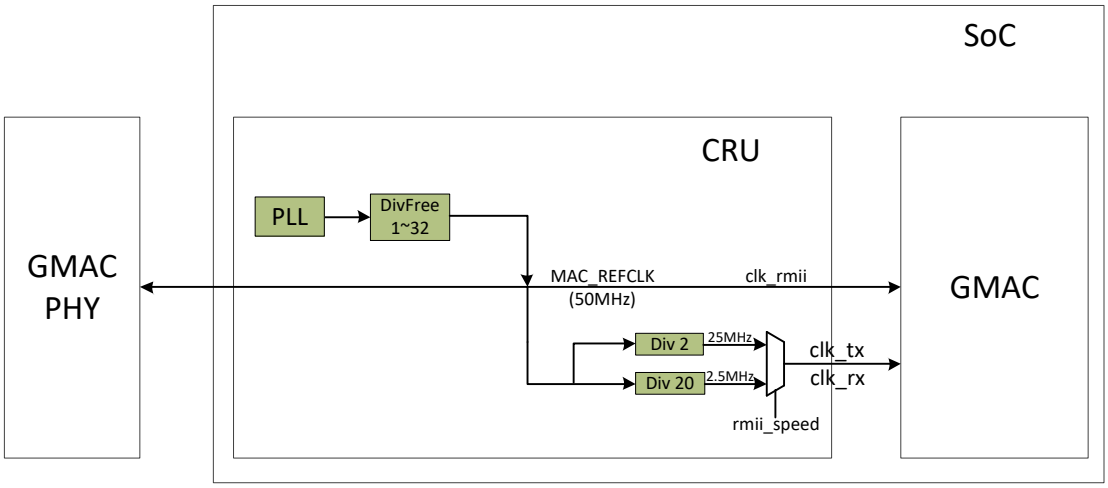

Fig. 25-11 RMII Clock Architecture When Clock Source From CRU

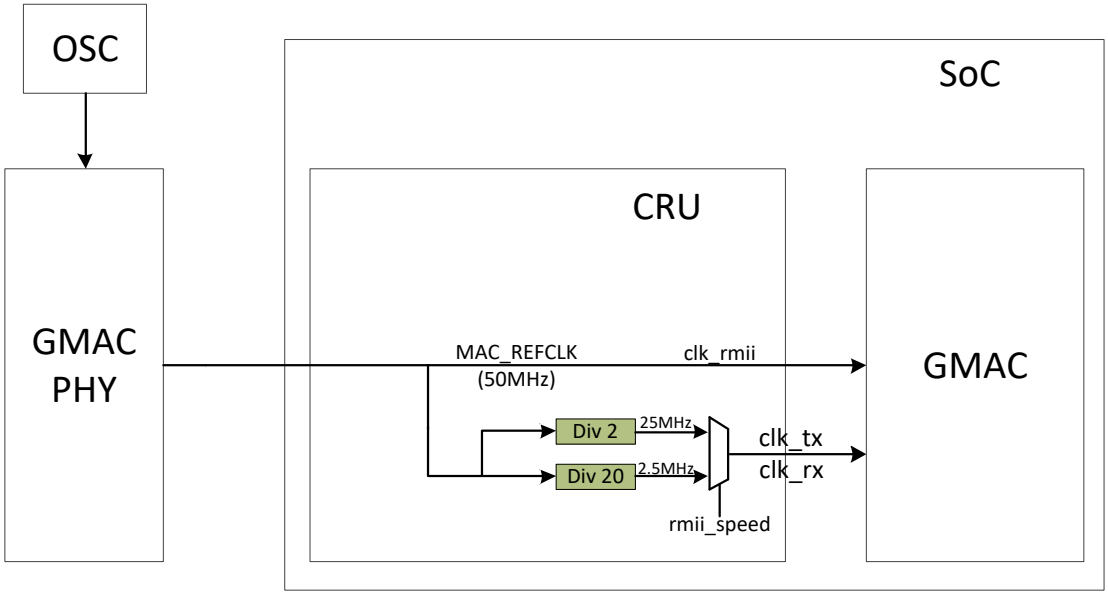

Fig. 25-12 RMII Clock Architecture When Clock Source From External OSC

In RGMII mode, clock architecture only supports that TX clock source is from CRU as following figure.In order to dynamically adjust the timing between TX/RX clocks with data, delayline is integrated in TX and RX clock path. Register SYS_GRF_SOC_CON7[5:2] can enable the delayline and SYS_GRF_SOC_CON8[15:0]/SYS_GRF_SOC_CON9[15:0] is used to determine the delay length. There are 200 delay elements in each delayline.

# Chapter 26 SAR-ADC

## 26.1 Overview

The ADC is an 8-channel single-ended 12-bit Successive Approximation Register (SAR) A/D Converter. It uses the supply and ground as its reference which avoid the use of any external reference. It converts the analog input signal into 12-bit binary digital codes at maximum conversion rate of 1MSPS with 20MHz A/D converter clock. The input range is typically 0V to 1.8V.

SAR-ADC controller supports the following features:

- Support single mode and series conversion mode.
- In single mode, the conversion operates once each software access.
- In series conversion, controller samples each channel then loops until software stop conversion.
- High/low threshold can be set, higher/lower/between high-low-threshold interrupt can be enabled

## 26.2 Block Diagram

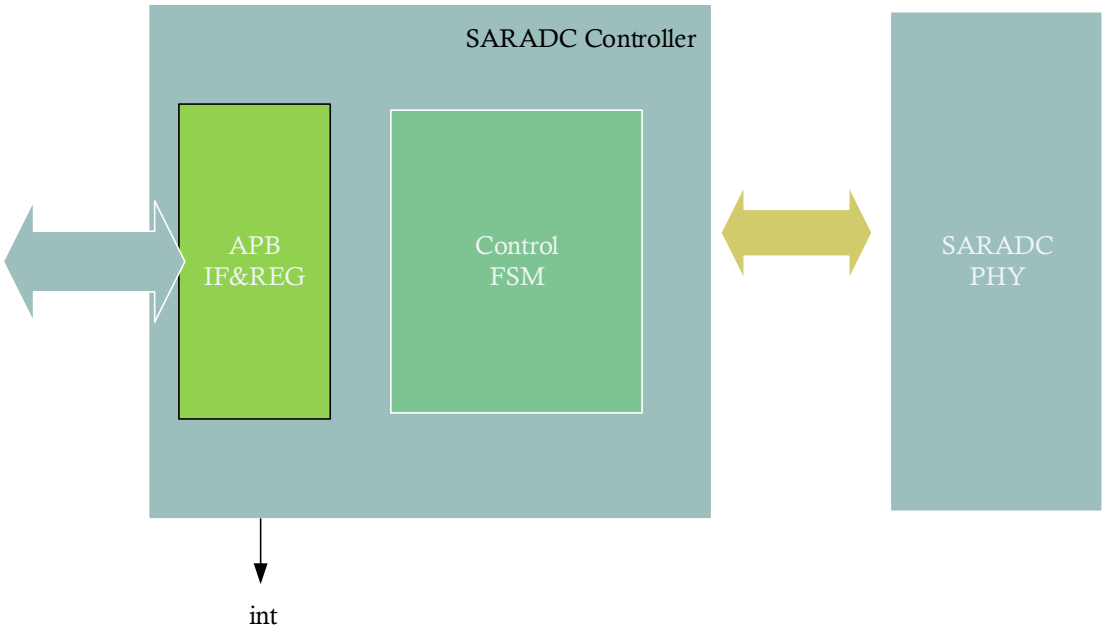

Fig. 26-1 SAR-ADC Block Diagram

SAR-ADC block shows in Fig.1-1. This includes:

- APB Interface
- Control FSM
- SAR-ADC PHY

Software can configure SAR-ADC controller by APB interface, then the inter FSM will communicate with SAR-ADC PHY for limited timing request.

## 26.3 Function Description

SAR-ADC block includes controller and PHY, user cannot directly access SAR-ADC PHY. Software access the SAR-ADC through SAR-ADC controller by APB interface. SAR-ADC controller will sample the conversion result from SAR-ADC PHY.

## 26.4 Register Description

### 26.4.1 Registers Summary

| Name | Offset | Size | Reset Value | Description |
|---|---|---|---|---|
| SARADC_CONV_CON | 0x0000 | W | 0x00000000 | Conversion control |

Copyright 2022 © Rockchip Electronics Co., Ltd.

| Name | Offset | Size | Reset Value | Description |
|---|---|---|---|---|
| SARADC_T_PD_SOC | 0x0004 | W | 0x00026000 | Timing control for PD to SOC |
| SARADC_T_AS_SOC | 0x0008 | W | 0x00000005 | Timing control for assert SOC |
| SARADC_T_DAS_SOC | 0x000C | W | 0x00000007 | Timing control from dis-assert SOC to change channel |
| SARADC_T_SEL_SOC | 0x0010 | W | 0x00000003 | Timimg control from change channel sel to assert SOC |
| SARADC_HIGH_COMP0 | 0x0014 | W | 0x00000000 | High threshold for ADC output data |
| SARADC_HIGH_COMP1 | 0x0018 | W | 0x00000000 | High threshold for ADC output data |
| SARADC_HIGH_COMP2 | 0x001C | W | 0x00000000 | High threshold for ADC output data |
| SARADC_HIGH_COMP3 | 0x0020 | W | 0x00000000 | High threshold for ADC output data |
| SARADC_HIGH_COMP4 | 0x0024 | W | 0x00000000 | High threshold for ADC output data |
| SARADC_HIGH_COMP5 | 0x0028 | W | 0x00000000 | High threshold for ADC output data |
| SARADC_HIGH_COMP7 | 0x0030 | W | 0x00000000 | High threshold for ADC output data |
| SARADC_HIGH_COMP8 | 0x0034 | W | 0x00000000 | High threshold for ADC output data |
| SARADC_HIGH_COMP9 | 0x0038 | W | 0x00000000 | High threshold for ADC output data |
| SARADC_HIGH_COMP10 | 0x003C | W | 0x00000000 | High threshold for ADC output data |
| SARADC_HIGH_COMP11 | 0x0040 | W | 0x00000000 | High threshold for ADC output data |
| SARADC_HIGH_COMP12 | 0x0044 | W | 0x00000000 | High threshold for ADC output data |
| SARADC_HIGH_COMP13 | 0x0048 | W | 0x00000000 | High threshold for ADC output data |
| SARADC_HIGH_COMP14 | 0x004C | W | 0x00000000 | High threshold for ADC output data |
| SARADC_HIGH_COMP15 | 0x0050 | W | 0x00000000 | High threshold for ADC output data |
| SARADC_LOW_COMP0 | 0x0054 | W | 0x00000000 | Low threshold for ADC output data |
| SARADC_LOW_COMP1 | 0x0058 | W | 0x00000000 | Low threshold for ADC output data |
| SARADC_LOW_COMP2 | 0x005C | W | 0x00000000 | Low threshold for ADC output data |
| SARADC_LOW_COMP3 | 0x0060 | W | 0x00000000 | Low threshold for ADC output data |
| SARADC_LOW_COMP4 | 0x0064 | W | 0x00000000 | Low threshold for ADC output data |
| SARADC_LOW_COMP5 | 0x0068 | W | 0x00000000 | Low threshold for ADC output data |
| SARADC_LOW_COMP6 | 0x006C | W | 0x00000000 | Low threshold for ADC output data |
| SARADC_LOW_COMP7 | 0x0070 | W | 0x00000000 | Low threshold for ADC output data |

### 26.4.2 Detail Register Description

**SARADC_CONV_CON**

Address: Operational Base + offset (0x0000)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:16 | WO | 0x0000 | write_enable<br>Write enable for lower 16bits, each bit is individual.<br>1'b0: Write access disable<br>1'b1: Write access enable |
| 15:10 | RO | 0x00 | reserved |
| 9 | RW | 0x0 | int_lock<br>This is used to lock the sample data when interrupt happened.<br>1'b1: Enable lock.<br>1'b0: Disable lock. |
| 8 | RW | 0x0 | as_pd_mode<br>If this bit is set to 1'b1, each time conversion ends, PD will be asserted. Then next time conversion starts, PD will be set to low auto automaticly. This is not used in single mode. |
| 7 | W1C | 0x0 | end_conv<br>End conversion, this is not used when CONV_CON[5] is set to 1'b1. If this bit set to 1'b1, PD will set to 1'b1 after the last conversion and this bit will be cleared to 1'b0. |
| 6 | RW | 0x0 | auto_channel_mode<br>Auto channel mode.<br>If this is enable, channel will be round auto according which is set in AUTO_CH_EN. |
| 5 | RW | 0x0 | single_pd_mode<br>Single conversion mode. If this bit is set to 1, conversion only operate once, then PD single will be set to 1. |
| 4 | W1C | 0x0 | start_adc<br>Enable ADC, if this bit set to one, conversion will start. Then this bit will be clear to 0. |
| 3:0 | RW | 0x0 | channel_sel<br>Channel for SARADC, 8 channels are supported. This fileld is not used when CONV_CON[6] is set to 1.<br>4'd0: sel channel 0.<br>4'd1: sel channel 1.<br>4'd2: sel channel 2.<br>4'd3: sel channel 3.<br>4'd4: sel channel 4.<br>4'd5: sel channel 5.<br>4'd6: sel channel 6.<br>4'd7: sel channel 7. |

## 26.5 Timing Diagram

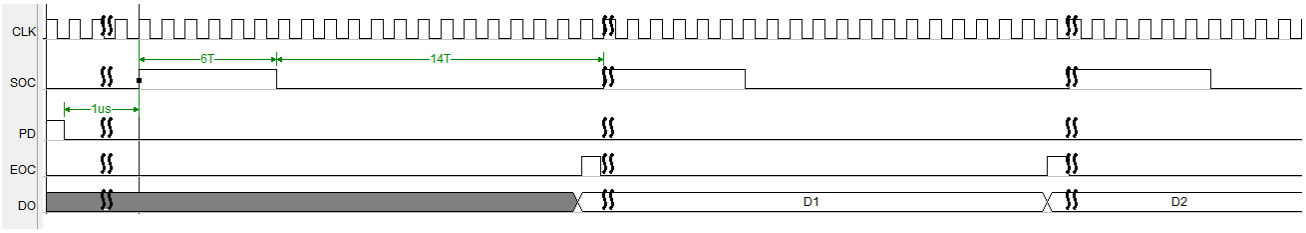

Fig. 26-2 SAR-ADC Timing Diagram

SAR-ADC timing diagram is shown in Fig.1-2. When PD (power down) comes to low, wait 1us then assert SOC to start conversion. SOC should hold for 6 clock cycles (CLK), then after 14 clock cycle EOC pulse with conversion data (DO). CLK is suggested to be 20MHz, if frequency could not meet, set frequency close to 20MHz but not over 20MHz.

Don't need to care the channel changing, this will be met by internal FSM. Also if software want to end conversion by setting register SARADC_CONV_CON, PD may not be asserted immediately but wait the latest conversion ends.

## 26.6 Application Notes

**Steps of ADC conversion in series conversion mode:**

- Decide which channel should be used and whether auto_channel mode should be set. In auto_channel mode channel will be changed from 0-7 then to 0. Please refer to SARADC_CONV_CON register.
- Set SARADC_CONV_CON[4] to 1'b1, then conversion will start.
- If conversion wants to be ended, set SARADC_CONV_CON[7] to 1'b1.
- Conversion could be read from SARADC_DATAn (n is from 0-7).
- If threshold compare interrupt wants to be used, high/low threshold could be set, and interrupt should be set as application.
- If auto_channel mode is not set, you could set the channel as application.

**Steps of adc conversion in single mode:**

- Decide which channel should be used and set SARADC_CONV_CON[3:0].
- Set SARADC_CONV_CON[5] to 1'b1.
- Set SARADC_CONV_CON[4] to 1'b1, then conversion will start.
- Conversion only operates once then ends. PD will be asserted and PD status could be got by reading SARADC_STATUS.
- Conversion could be read from SARADC_DATAn (n is from 0-7).

# Chapter 27 Digital Audio Codec

## 27.1 Overview

Digital Audio Codec is a 16-bit digital audio encoder which supports multiple sample rates. It is mainly composed of digital DAC. The aim of digital DAC is to process the data received from I2S/PCM interface through filters, volume control and modulation.
The Digital Audio Codec supports the following features.

- Support 8-bit APB bus slave interface
- Support 2-channel digital DAC
- Support I2S/PCM interface
- Support I2S/PCM master and slave mode
- Support 2-channel audio receiving in I2S mode
- Support 2-channel audio receiving in PCM mode
- Support I2S normal, left and right justified mode serial audio data transfer
- Support PCM early, late1, late2, late3 mode serial audio data transfer
- Support MSB or LSB first serial audio data transfer
- Support configurable SCLK and LRCK polarity
- Support 16 bit sample resolution
- Support programmable left and right channel exchangeable in I2S mode and PCM mode
- Support three modes of mixing for every digital DAC channel
- Support volume control
- Support programmable negative and positive volume gain

## 27.2 Block Diagram

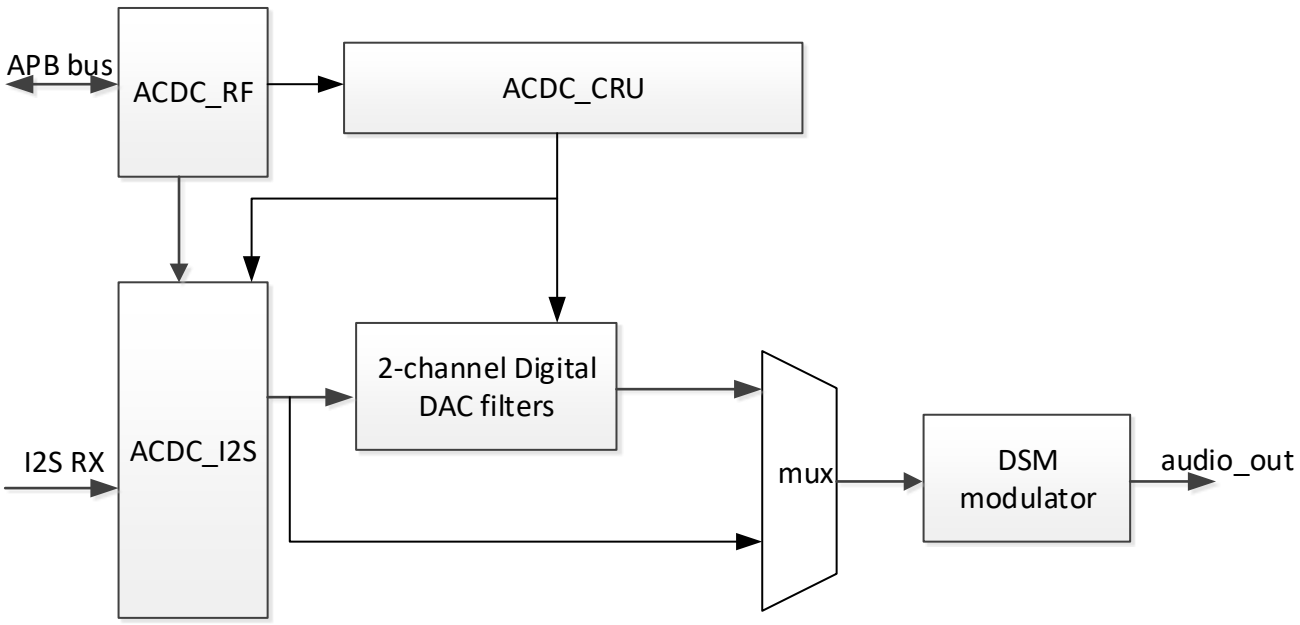

Fig. 27-1 Digital Audio Codec Block Diagram

**ACDC_RF**
The ACDC_RF implements the 8-bit APB slave operation through APB bus. It is responsible for configuring the operation registers of other modules.
**ACDC_CRU**
The ACDC_CRU implements clock and reset generation function. It is responsible for generating sample clock, digital DAC operation clock and I2S operation clock.
**Digital DAC**
There are 2 digital DAC channels. The digital DAC receives audio data from ACDC_I2S module. It includes one CIC filter, one high-pass filter, several low-pass decimation filters

Copyright 2022 © Rockchip Electronics Co., Ltd. 

and other audio signal processing related modules. The output of digital DAC is sent to DSM modular before transmitting outside.

**ACDC_I2S**

The I2S/PCM audio interface can be configured to master mode or slave mode. In Master Mode, SCLK and LRCK are configured as output. In slave mode, SCLK and LRCK are configured as input. The ACDC_I2S module can only operate in RX mode. When in RX mode, it receives audio data from I2S RX interface and sends it to digital DAC.

**DSM Modulator**

It is a modulator that converts 16 bits audio sample data to 1 bit audio data.

# 27.3 Function description

The I2S/PCM interface of Digital Audio Codec is connected to the I2S3 controller. Please refer to the I2S chapter for detailed information about I2S and PCM format that Digital Audio Codec supports.

## 27.3.1 Filters of Digital DAC

I2S module receives two-channel audio data from I2S RX interface and drives it to the digital DAC which supports mixing function or directly to the DSM modulator. How to pour 2-channel audio data into 2-channel digital DAC can be achieved by programming mixing mode.

The 2-channel digital DAC includes a high-pass filter and a maximum of 5 half-band filters. The high-pass filter is used to filter DC components in audio data stream. Result of high-pass filter is sent to the digital DAC volume control module. The input of 5 half-band filters comes from output of volume control module with each perform 2-times interpolation. But not all of them are working all the time. How many of them are needed to work depends on the sample rate of digital DAC. The result of half-band filters is sent to a modulator.

## 27.3.2 Volume Control

For digital DAC, output of high-pass filters is fed into volume control module. The volume control module inside digital DAC contains several sub-modules such as peak detect, frequency cross zero detect, LIMITER and digital gain control. It can be digitally attenuated over a range of -96dB~0dB in 0.375dB/step for negative gain and amplified over a range of 0dB~96dB in 0.375dB/step for positive gain. Whether is attenuated or amplified can be software programmed.

# 27.4 Register Description

## 27.4.1 Internal Address Mapping

Slave address can be divided into different length for different usage, which is shown as follows.

## 27.4.2 Registers Summary

| Name | Offset | Size | Reset Value | Description |

## 27.5 Interface Description

The I2S RX interface of Digital Audio Codec is connected to the TX interface of I2S3 when SYS_GRF_SOC_CON6[11] is set to 1'b1.
When operating in audio PWM mode 0 or 1, Digital Audio Codec outputs two pairs of differential signals encoded in PWM format. The following table shows the Digital Audio Codec interface description for audio PWM mode.

Table 27-1 Digital Audio Codec Interface Description

| Module Pin | Direction | Pad Name | IOMUX Setting |
|---|---|---|---|
| AUDIO_PWM_L_P | O | GMAC1_RXD2/SDIO_D2_M1/I2S3_LRCK/AUDDSM_LP/FSPI_D2_M2/UART8_TX_M1/SPI4_CLK_M1/GPIO3_A2_u | BUS_IOC_GPIO3A_IOMUX_SEL_L[11:8]=4'h4 |
| AUDIO_PWM_L_N | O | GMAC1_TXD3/SDIO_D1_M1/I2S3_SCLK/AUDDSM_LN/FSPI_D1_M2/I2C6_SCL_M4/PWM11_IR_M0/SPI4_MOSI_M1/GPIO3_A1_u | BUS_IOC_GPIO3A_IOMUX_SEL_L[7:4]=4'h4 |
| AUDIO_PWM_R_P | O | GMAC1_TXCLK/SDIO_CMD_M1/I2S3_SDI/AUDDSM_RP/UART8_RTSN_M1/SPI4_CS1_M1/GPIO3_A4_d | BUS_IOC_GPIO3A_IOMUX_SEL_H[3:0]=4'h4 |
| AUDIO_PWM_R_N | O | GMAC1_RXD3/SDIO_D3_M1/I2S3_SDO/AUDDSM_RN/FSPI_D3_M2/UART8_RX_M1/SPI4_CS0_M1/GPIO3_A3_u | BUS_IOC_GPIO3A_IOMUX_SEL_L[15:12]=4'h4 |

## 27.6 Application Notes

### 27.6.1 Software Application Notes

Steps to configure Digital DAC to work in audio PWM mode 0 are as follows.
1. Program CRU in the SOC system to achieve the operation frequency of Digital DAC.
2. Program ACDCDIG_DACINT_DIV to 0x07.
3. Program ACDCDIG_DACCLKCTRL to 0x3d.
4. Program ACDCDIG_DACSCLKRXINT_DIV if Digital DAC I2S RX acts as master.
5. Program ACDCDIG_DACPWM_CTRL to 0x58.
6. Program ACDCDIG_I2S_CKR0 and ACDCDIG_I2S_CKR1 to set I2S RX related registers.
7. Program ACDCDIG_I2S_CLR to clear RX logic.

Copyright 2022 © Rockchip Electronics Co., Ltd.

8. Program ACDCDIG_I2S_RXCR0 and ACDCDIG_I2S_RXCR1.
9. Program SYS_GRF_SOC_CON6[11] to 1'b1 and program registers of I2S3 that is connected to Digital Audio Codec. Don't start transfer at this time.
10. Program DAC related registers such as ACDCDIG_DACHPF, ACDCDIG_DACVUCTL and ACDCDIG_DACCFG1 to achieve basic configuration.
11. Program ACDCDIG_I2S_XFER to start I2S RX.
12. Program registers of I2S3 outside Digital Audio Codec to start TX.
13. Program ACDCDIG_DACDIGEN to enable digital DAC channels. From now on, the Digital Audio Codec begins to work.

Steps to configure Digital Audio Codec to end audio PWM mode 0 transfer are as follows.
1. Program registers of I2S3 to stop TX and ACDCDIG_I2S_XFER to stop RX.
2. Program ACDCDIG_DACPWM_CTRL to 0x0.
3. Program ACDCDIG_DACDIGEN to disable digital DAC channels.
4. Program ACDCDIG_DACCLKCTRL to 0x0. Wait ACDCDIG_DACCLKCTRL.dac_sync_status until read back to be 1'b0.

Steps to configure Digital DAC to work in audio PWM mode 1 are as follows.
1. Program CRU in the SOC system to achieve the operation frequency of Digital DAC.
2. Program ACDCDIG_DACCLKCTRL to 0x3d.
3. Program ACDCDIG_DACSCLKRXINT_DIV if Digital DAC I2S RX acts as master.
4. Program ACDCDIG_DACPWM_CTRL to 0x68.
5. Program ACDCDIG_I2S_CKR0 and ACDCDIG_I2S_CKR1 to set I2S RX related registers.
6. Program ACDCDIG_I2S_CLR to clear RX logic.
7. Program ACDCDIG_I2S_RXCR0 and ACDCDIG_I2S_RXCR1.
8. Program SYS_GRF_SOC_CON6[11] to 1'b1 and program registers of I2S3 to start TX.
9. Program ACDCDIG_I2S_XFER to start I2S RX. From now on, the Digital Audio Codec begins to work.

Steps to configure Digital Audio Codec to end audio PWM mode 1 transfer are as follows.
1. Program registers of I2S3 to stop TX and ACDCDIG_I2S_XFER to stop RX.
2. Program ACDCDIG_DACPWM_CTRL to 0x0.
3. Program ACDCDIG_DACCLKCTRL to 0x0. Wait ACDCDIG_DACCLKCTRL.dac_sync_status until read back to be 1'b0.

# Chapter 28 Voice Activity Detect (VAD)

## 28.1 Overview

Voice Activity Detect (VAD) is used to detect the amplitude of voice which is received by Analog Mic, I2S Digital Mic or PDM digital Mic when SoC is in low power mode. If the amplitude of voice is over threshold, the VAD will assert interrupt to wake up SoC, then SoC will exit low power mode.

VAD supports the following features:

- Support AHB bus interface
- Support read voice data from I2S1, PDM0
  - Support to configure the voice source address
  - Support to configure increment or fixed for the direction of voice data address
  - Support DMA request and acknowledge
  - Support transfer 1~8 burst per DMA request
  - Support read 1~8 Mic voice data, and only support single Mic voice detection, user can select any Mic voice data to detect the amplitude of voice
  - Support 16/24 bits voice data
- Support voice amplitude detection
  - Support an Amplifier for the voice data
  - Support a IIR high pass filter for the voice frequency band, and the filter coefficient can be configured
  - Support a voice detect threshold that take the ambient noise to account
- Support Multi-Mic array data storing
  - Buffer memory is shared with Internal SRAM
  - The start and end address of storing can be configured
  - When current storing address is up to end address, it will loop to start address and overlap previous data, it will also assert a flag
  - Support 3 data storing mode: mode 0 start storing data after the voice detect event, mode 1 start storing after VAD is enabled and mode 2 do not storing data
  - Support storing data through bus or ram write interface
- Support a level combined interrupt
  - Support voice detect interrupt
  - Support time out interrupt
  - Support transfer error interrupt
  - Support data transfer interrupt

## 28.2 Block Diagram

VAD comprises with:

- AHB_MASTER: AHB Master Interface
- AHB_SRAM_IF: AHB Slave Interface
- VAD_REG_BANK: Register bank
- DMAC_ENGINE: DMA control engine
- VAD_DET: Voice detection

Copyright 2022 © Rockchip Electronics Co., Ltd.

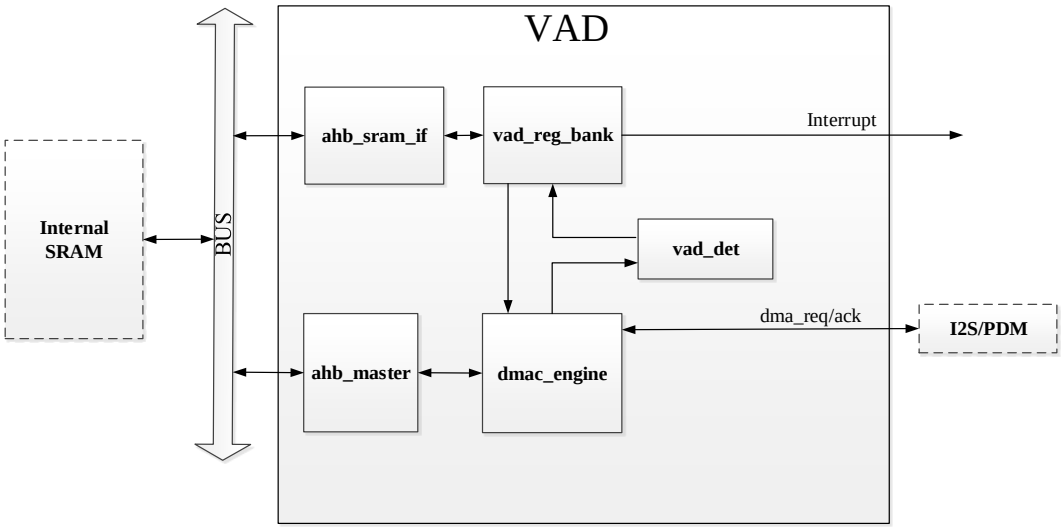

Fig. 28-1 VAD Block Diagram

# 28.3 Function Description

## 28.3.1 DMAC_ENGINE

DMAC_ENGING is used to read voice data from one of I2S_8CH_0 or PDM, and it can store all channels data to Internal SRAM. If the bus can be access, user can configure to store through bus. Otherwise user should configure to store through ram write interface. When VAD is working, user can change the data storing mode dynamically. The storing address can be continuous transition or be spitted.

The voice data can be 16 or 24 bits:

- When it's 16 bits, it must be half word transfer mode that low 16 bits in a word for left channel and high 16 bits in a word for right channel.
- When it's 24bits, it must be word transfer mode that only 24 bits data is valid in a word, and it support left or right justified.

DMAC_ENGING also select and send one channel data to vad_det for voice detection. vad_det only support 16 bits data to detect the amplitude of voice, so when the voice data is 24 bits, user can use the high or low 16 bits in 24 bits.

- When use high bits, the data value will be divided by 256.
- When use low bits, the data value will be saturation to 16 bits.

## 28.3.2 VAD_DET

VAD_DET is used to detect the amplitude of voice.

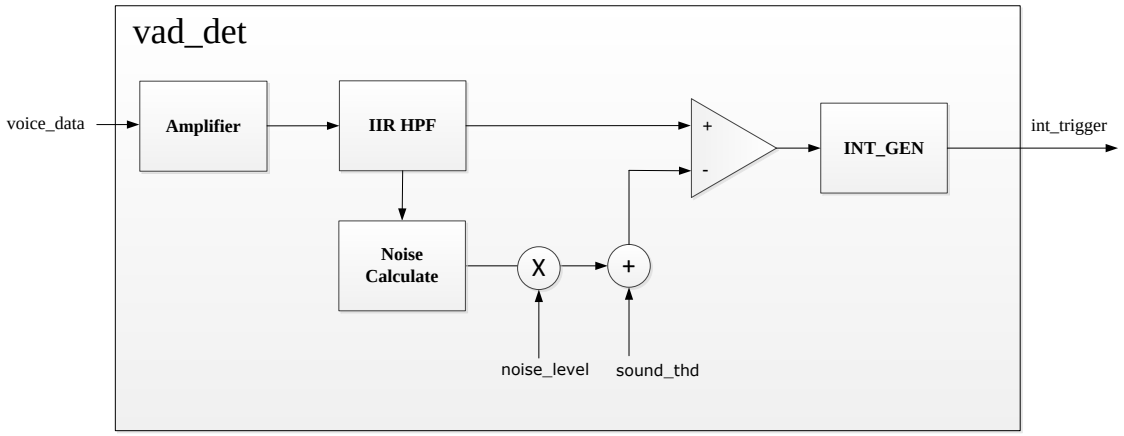

Fig. 28-2 VAD_DET Block Diagram

**Amplifier**

voice_amplitude_amplified=gain*voice_amplitude_original/8.

**IIR HPF**

There is a high pass filter for the human voice frequency band, the filter is a two order direct I type IIR. The following formula describes:

y(n)=-a1*y(n-1)-a2*y(n-2)+b0*x(n)+b1*x(n-1)+b2*x(n-2)

The coefficient a1, a2, b0, b1 and b2 are all quantified by multiplying 16384 and represented as 16 bits, the result in follow registers that can be configured: iir_anum_0, iir_anum_1, iir_anum_2, iir_aden_1 and iir_aden_2.

The output of HPF need some time to achieve convergence after VAD is enabled.

**Noise Calculate**

VAD support a voice detection threshold that take the ambient noise to account:

- VAD calculate the average amplitude of voice data within noise_sample_num samples, the result is regard as the noise value of one frame. The noise value of last 128 frames also can be configured directly.
- VAD find the minimum noise value within noise_frm_num frames, the result is regard as the noise_min(minimum noise value).User can configure min_noise_find_mode to change the mode to find the minimum noise.
- The noise_min will be smooth updated to noise_abs(current noise value), the formula is as follow: noise_abs= (noise_abs * noise_alpha + noise_min * (256-noise_alpha)/256. noise_abs will be updated once every frame. noise_abs also can be configured directly, and it is not clear until VAD is reset.

**Voice Detect Threshold**

The final threshold is sound_thd + noise_abs * noise_level.

**INT_GEN**

VAD support 3 modes to assert the voice detection interrupt.

- Normal mode: When equal or more than a number (vad_con_thd) of continuous samples over the threshold, the voice detection interrupt will be asserted. The vad_con_thd can be configured by register.
- Allow an exception mode: base on normal mode, it can be configured to allow exceptions during continuous sample judgment. The exception number can be configured by register. When the exceptions is more, the voice detect condition is less strict.
- Accumulating mode: A counter is used for accumulating, the counter will plus 1 when current sample is over threshold (it will not plus when it reach maximum value 256), the counter will minus 1 when current sample is not over threshold (it will not minus when it reach 0); When the counter is equal or more than a number (vad_con_thd), the voice detection interrupt will be asserted. Compare with normal mode, the voice detect condition is less strict when use the same value of vad_con_thd.

# 28.5 Application Notes

## 28.5.1 VAD usage flow

VAD usage flow is shown as following figures.

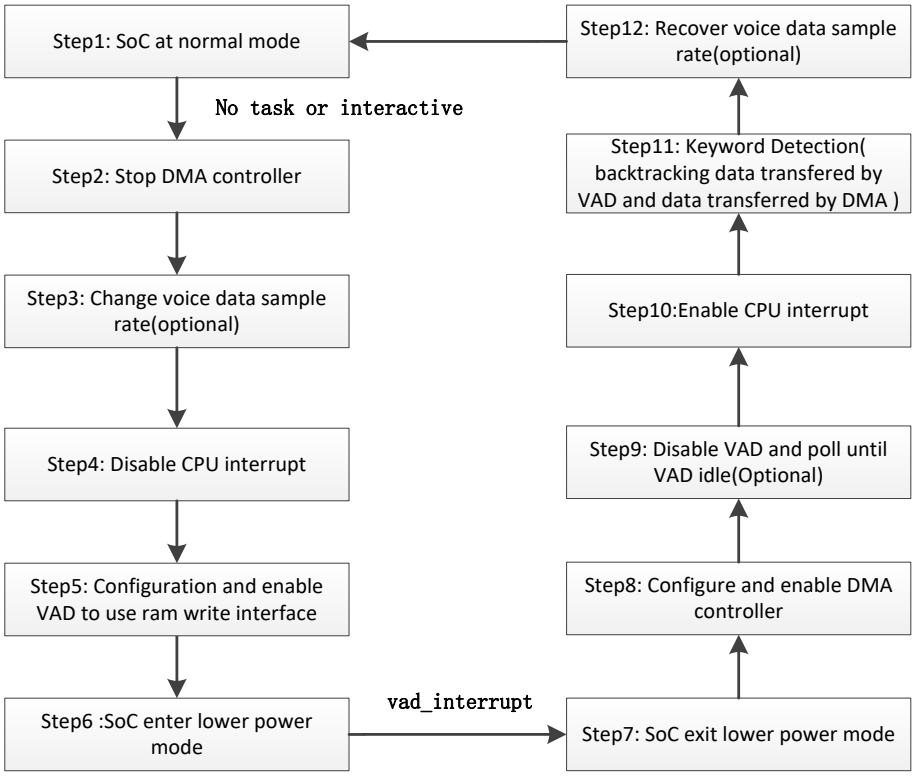

Fig. 28-3 VAD usage flow (only used ram write interface mode)

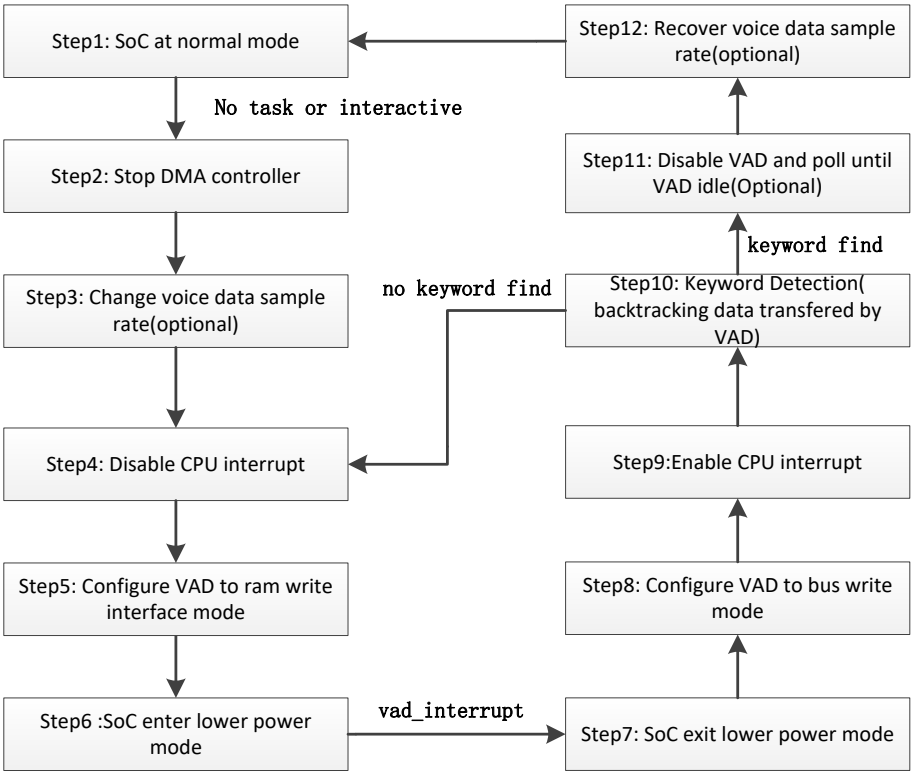

Fig. 28-4 VAD usage flow (use bus mode and ram write interface mode)

- Step3, step12 are optional, user should consider the power consumption and keyword detection accuracy for these steps.
- Disable VAD step is optional, user can keep VAD working, and use it as a DMA Controller.

## 28.5.2 VAD configuration usage flow

- Set VAD_VS_ADDR.vs_addr=I2S_8CH_0 base address + I2S_8CH_INCR_RXDR.
- Set VAD_RAM_BEGIN_ADDR.ram_begin_addr and VAD_RAM_END_ADDR.ram_end_addr, the address should match with the Internal SRAM sharing scheme.
- Set to bus write mode or ram interface mode when enable VAD
  Set VAD_AUX_CON0.bus_write_en=0, and VAD_AUX_CON0.dis_ram_itf =0 toenable VAD as ram interface write mode.
  Set VAD_AUX_CON0.bus_write_en=1, and VAD_AUX_CON0.dis_ram_itf =1 to enable VAD as bus write mode.
- Adjust the sensitivity of voice activity detect by setting follow registers:
  VAD_DET_CON0.noise_level
  VAD_DET_CON0.vad_con_thd
  VAD_DET_CON0.dis_vad_con_thd
  VAD_DET_CON0.vad_thd_mode
  VAD_DET_CON1.noise_sample_num
  VAD_DET_CON1.sound_thd
  VAD_DET_CON2.noise_frm_num
  VAD_DET_CON2.noise_alpha
- Set the iir_anum_0~3 and iir_aden_1~2 to adjust the IIR HPF coefficient.
  For 48Khz sample rate:
  iir_anum_0: 0x382d
  iir_anum_1: 0x8fa5
  iir_anum_2: 0x382d
  iir_aden_1: 0x909b
  iir_aden_2: 0x3150
  For 16Khz sample rate (default):
  iir_anum_0: 0x3bf5
  iir_anum_1: 0x8817
  iir_anum_2: 0x3bf5

Copyright 2022 © Rockchip Electronics Co., Ltd. 

iir_aden_1: 0x8858
iir_aden_2: 0x382b
For 8Khz sample rate:
iir_anum_0: 0x3e9f
iir_anum_1: 0x82c2
iir_anum_2:0x3e9f
iir_aden_1: 0x82c9
iir_aden_2: 0x3d46

- Set DET_CON5.noise_abs to ambient noise which is calculated by software.
  Set VAD_NOISE_DATA+offset to initial the noise data of all frames. The frame number is VAD_DET_CON2.noise_frm_num.
  The first frame noise data address is VAD_NOISE_DATA, the second frame noise data address is VAD_NOISE_DATA+0x4, and so on.
- Set VAD_INT.vad_det_int_en=0x1 to enable the interrupt.
- Set VAD_AUX_CONTROL to disable detection at the beginning after VAD is enabled.
  Set sample_cnt_en=0x1
  Set int_trig_ctrl_en=0x1
  Set int_trig_valid_thd to appropriate value, it recommended configuration to 4ms.
  For 48Khz sample rate: int_trig_valid_thd= 0xc0
  For 16Khz sample rate: int_trig_valid_thd= 0x40
  For 8Khz sample rate: int_trig_valid_thd= 0x20
- Set VAD_CONTROL register:
  Set source_select=0x1, select I2S_8CH_0
  Set source_burst=0x3, select INCR4 burst type
  Set source_burst_num=0x0, select 1 burst transfer per DMA request
  Set vad_mode=0x0, select Mode 0
  Set voice_channel_num=0x7, all voice channel number is 8
  Set voice_channel_bitwidth=0x0, voice data width is 16 bits
  Set vad_det_channel=0x0, use channel 0 to voice activity detect
  Set vad_en=0x1, enable VAD
- After above setting, VAD will start to work and system can enter low power mode.
  When VAD is working, user can configure the VAD_AUX_CON0.bus_write_en and VAD_AUX_CON0.ram_itf_dis to change the data storing mode dynamically. The storing address can be continuous transition or be spitted. It's controlled by following bits:
  VAD_AUX_CON0.bus_write_addr_mode
  VAD_AUX_CON0. bus_write_rework_addr_mode
  VAD_AUX_CON0. ram_write_rework_addr_mode

### 28.5.3 Data Transfer Interrupt usage flow

When VAD is working at bus write mode. User can get data transfer interrupt by following additional configuration.

- Set VAD_AUX_CONTROL.data_trans_trig_int_en=0x1
- Set VAD_AUX_CONTROL.data_trans_kbyte_thd at appropriate value
- Set VAD_INT.vad_data_trans_int_en=0x1

### 28.5.4 Timeout configuration usage flow

- Set VAD_TIMEOUT.idle_timeout_thd=0xfffff, set VAD_TIMEOUT.idle_timeout_en=0x1, set VAD_INT.idle_timeout_int=0x1. After above setting, a counter is increase at AHB clock when dmac_engine is idle, the counter will be clear to 0 once dmac_engine start to read voice data. An interrupt will be asserted when the counter up to idle_timeout_thd. This idle timeout is used for I2S/PDM work fail (Don't assert DMA request for a long time).
- Set VAD_TIMEOUT.work_timeout_thd=0x3ff, set VAD_TIMEOUT.work_timeout_en=0x1, set VAD_INT.work_timeout_int=0x1. After above setting, a counter is increase at AHB clock when dmac_engine is busy, the counter will be clear to 0 once dmac_engine is idle. An interrupt will be asserted when the counter up to work_timeout_thd. This work timeout is used for bus transmission congestion (a burst transferring is not completed for a long time).

# Chapter 29 CAN

## 29.1 Overview

CAN (Controller Area Network) bus is a robust vehicle bus standard designed to allow microcontrollers and devices to communicate with each other in applications without a host computer. It is a message-based protocol, designed originally for multiplex electrical wiring within automobiles to save on copper, but is also used in many other contexts.

## 29.2 Features

The features listed below which may or may not be present in actual product, may be subject to the third party licensing requirements. Please contact Rockchip for actual product feature configurations and licensing requirements.
CAN controller supports the following features:

- Support CAN 2.0B protocol
- Support 32-bit APB bus
- Support transmit or receive CAN standard frame
- Support transmit or receive CAN extended frame
- Support transmit or receive data frame, remote frame, overload frame, error frame and frame interval
- Support transmit or receive error count
- Support acceptance filtering
- Support Bit error, Bit stuffing error, Form error, ACK error and CRC error
- Support multiple types of interrupt and all interrupt can be masked
- Support CAN controller status query
- Support capture the bit position of arbitration section where the arbitration was lost
- Support error code check
- Support self-test mode
- Support single sample and three sample configurable
- Support SJW(Resynchronization Jump Width) configurable
- Support BRP(system prescale coefficient) configurable
- Support bit timing configurable
- Support loop-back mode for self-test operation
- Support silent mode for debug
- Support receive self-transmit data mode(rxstx_mode)
- Support TX data and RX data order select
- Support RX data cover mode
- Support auto retransmission mode
- Support auto bus on after bus-off state
- Support space_rx_mode
- Support transmitter delay compensation and SSP position configurable
- Support sleep mode
- Support timestamp
- Support transmit event FIFO
- Support 2 transmit buffers
- Support receive buffer/FIFO mode
- Support protocol exception event
- Support DMA

# 29.3 Function Description

## 29.3.1 Block Diagram

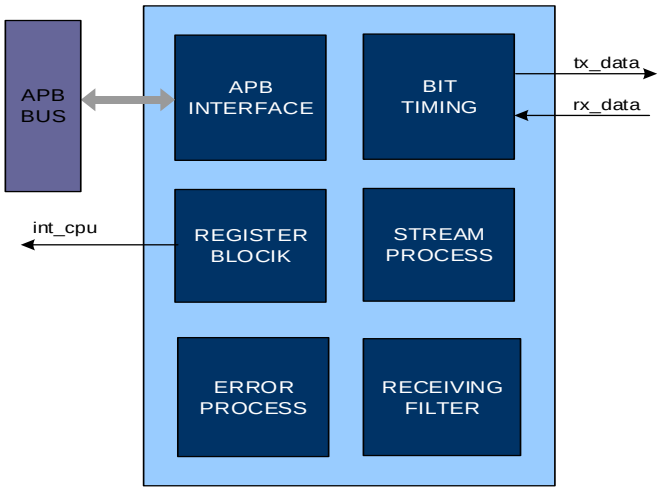

Fig. 29-1 CAN Controller Block Diagram

This version of CAN controller includes the previous version of CAN logic in compliance with old software application and new version of CAN logic with new software application.

## 29.3.2 ACCEPTANCE FILTER

The acceptance filter performs filtering using the acceptance ID register and the ID mask register. The acceptance filter uses multiple-time filtering. It includes the old version receiving filter and five addition ID filters. Each ID filter pair has a Filter Mask register and a Filter ID register. Each filter pair is controlled by corresponding FILTER CTRL bit in AFR register. For each pair using ID register and ID mask register (controlled by acceptance filter register) sampling all the bits of the ID, it is compared with the ID register. It is not a comparison every time a bit is sampled. And don't check the bit in the ID mask register that is 1. Once all the ID bits have passed the filtering, the controller considers the frame data as the desired ID, thereby performing the next operation.

## 29.3.3 BIT TIMING

### 29.3.3.1 Bit Timing Logic

The bit timing logic controls the sampling point position through the buffer bits in the timing register to ensure the accuracy of the data sampling. The bit timing logic receives the clock frequency division signal for identification, sets the bus timing parameters, establishes synchronization parameters, and adjusts the bus transmission rate. At the same time, the bus is monitored and the message to be sent is transmitted to the bus at the set timing. According to the provisions of the CAN protocol: the CAN bus is always at a high level when no message is sent, and the continuous recessive bit is monitored on the bus. At this time, the bus is in an idle state, and the arbitration priority is low, ready to receive data at any time. When the bus detects a transition from a recessive bit to a dominant bit, it is proved that the frame start bit starts transmitting, and the bus performs a hard synchronization in the bit start sync segment. Then, in the process of receiving the message, once the edge of the transition close to the sampling point is detected and the edge of the edge and the synchronization segment have a phase error lower than the synchronization width (SJW is taken when the value exceeds SJW), the controller executes once resynchronization, resynchronization can be performed multiple times during one data transmission.

### 29.3.3.2 Bit Timing Definition

The transmission time of each bit is divided into 4 parts:

$$t_{nbt} = t_{sync_seg} + t_{prop_seg} + t_{phase_seg1} + t_{phase_seg2}$$

$t_{sync_seg}$, $t_{prop_seg}$, $t_{phase_seg1}$ and $t_{phase_seg2}$ are integer multiples of the unit time($t_{sclk}$), and

Copyright 2022 © Rockchip Electronics Co., Ltd.

this unit time is a specific multiple of the system clock, which is determined by the division factor BRP in the bus timing register: 1. The counter is obtained by the BRP operation; 2. The system clock is counted by the counter; 3. When the limit is reached, a clock with a period of $t_{sclk}$ is generated.
In the system design, considering the cyclical occurrence of each time period, a state machine with three states is used in the bit timing design. The three states correspond to the sync segment(sync_seg) and the phase buffer segment 1 (phase_seg1=phase_seg1+prog_seg) and the phase buffer segment 2 (phase_seg2), respectively. Where PHASE_SEG1 range: 1~16; PHASE_SEG2 range: 1~8; BRP range: 1~64.

$$t_{sync_seg} = 1 \times t_{sclk}$$

$$t_{prop_seg} + t_{phase_seg1} = t_{sclk} \times (8 \times TSEG1.3 + 4 \times TSEG1.2 + 2 \times TSEG1.1 + TSEG1.0 + 1)$$

$$t_{phase_seg2} = t_{sclk} \times (4 \times TSEG2.2 + 2 \times TSEG2.1 + TSEG1.0 + 1)$$

Define a counter to count $t_{sclk}$. When the count reaches the TSEG1, TSEG2 defined in the bus timing register and the length of the synchronization segment defined in the design, the system will generate the corresponding transition conditions: go_seg1, go_seg2, go_sync. By judging these transition conditions, the control state machine cycles through the above three states.

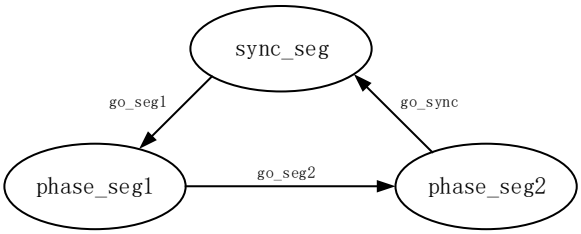

Fig. 29-2 Bit timing FSM

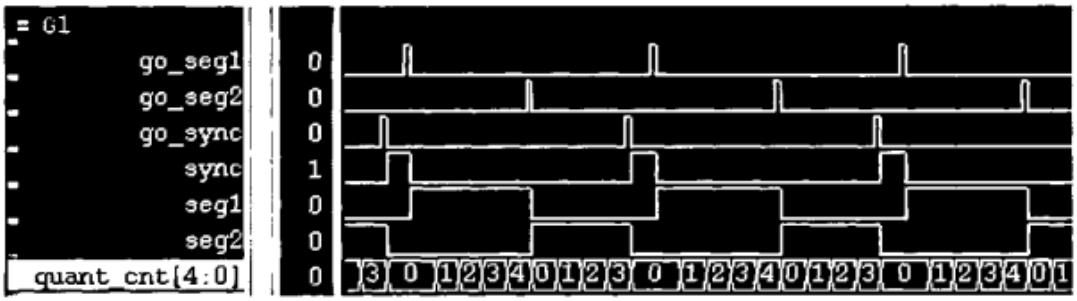

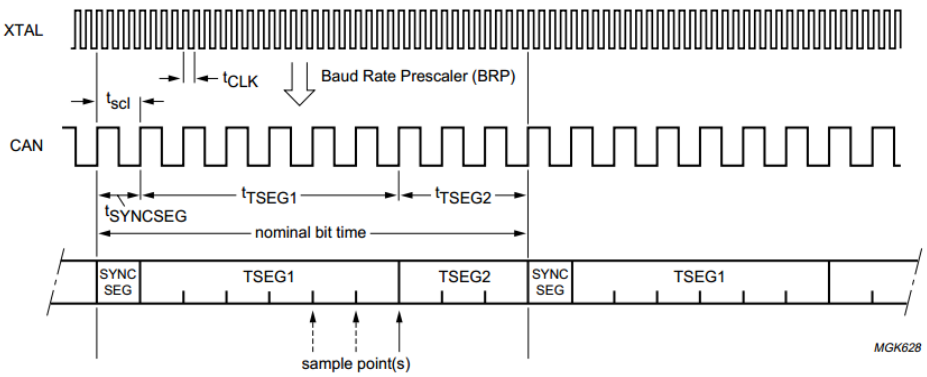

Fig. 29-3 Bit timing waveform diagram

#### 29.3.3.3 Sampling Point and Sending Point

**Sampling Point:** According to the agreement, the sample point should be between phase_seg1 and phase_seg2. It is designed to be in the position of phase_seg2 synchronization. The sampling pulse width is defined as one system clock cycle. Considering the accuracy of sampling, you can use the method of taking three samples to take the mean. The interval between each sample point is one $t_{sclk}$.

Copyright 2022 © Rockchip Electronics Co., Ltd.

Possible values are BRP = 000001, TSEG1 = 0101 and TSEG2 = 010.

Fig. 29-4 Three sampling diagram

**Sending Point:** The location of the transmit point should be at the beginning of each bit time according to the protocol, and it is designed to synchronize it with the go_sync signal. In addition, if it is in sync or resynchronize, transmit point will be valid immediately.

#### 29.3.3.4 Bit Synchronization

With the synchronization method, one or more nodes that satisfy the synchronization condition align their synchronization segments with the transmission data on the bus at a specific time. Synchronization occurs on the 1-to-0 transition edge in order to control the distance from the transition edge to the sample point. Two synchronization methods are defined in the CAN bus communication protocol: hard synchronization and resynchronization.

**Hard sync**: All nodes must be synchronized to the leading edge of the starting frame of the node that first started transmitting the message. At the beginning of each frame of data, a synchronization action is taken between the nodes.

Hard synchronization implementation method: determine whether the bus state meets the frame start condition specified in the protocol, and the node is not in the state of the data to be transmitted. At this time, a hard synchronization flag signal hard sync is generated, and the pulse width is a system clock; The hard sync entry is added to the control condition of the go_seg1 signal, and go_seg1 is valid immediately when the hard sync signal is '1'. Therefore, once the hard synchronization condition is met, the system enters the phase_seg1 segment, thereby achieving synchronization.

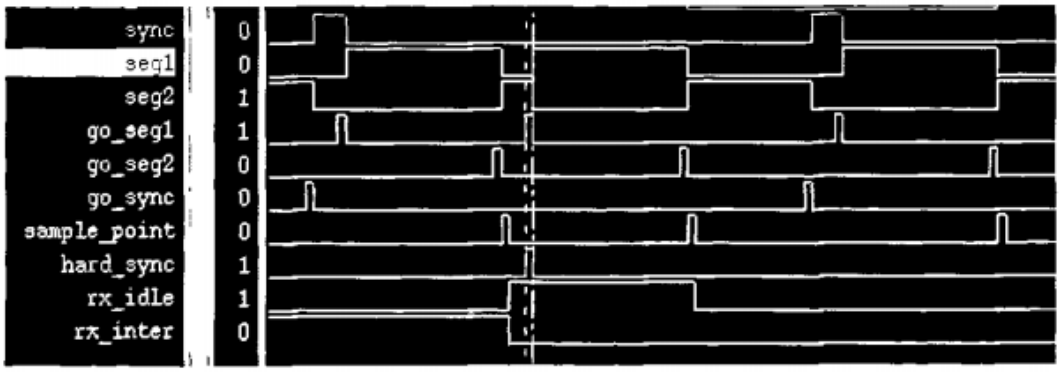

Fig. 29-5 Hard sync waveform diagram

**Resynchronization**: In addition to generating hard synchronization at the beginning of each frame of data, the CAN bus communication protocol also specifies the transmission of data for each frame. When the timing coordination between the nodes is not ideal, it will be resynchronized, so that the cooperation between the nodes is in a good state.

For the receiver, the bus changes it received should occur in the sync segment. Once the receiver's status violates this rule, the receiver will perform a resynchronization.

Two situations that require resynchronization:

- The jump of the bus value '1' to '0' occurs between the sync segment and the sample

Copyright 2022 © Rockchip Electronics Co., Ltd. 

point, which is a delay jump;
- The jump of the bus value '1' to '0' occurs between the sample point and the sync segment, which is an early jump.

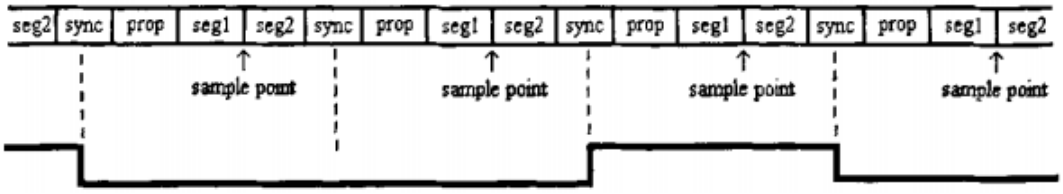

Fig. 29-6 Resynchronization

Resynchronization method:
1. Condition for resynchronization: the receiver is in a mode of receiving data (not inter-frame space or bus idle), and a resynchronization flag signal 'resync' is generated when a jump of the bus value '1' to '0' occurs;
2. According to the position of the resynchronization flag signal, it is determined that the abnormal jump is a delay jump or an early jump;
3. Counting the delay or the length of the advance by the counter;
4. In this bit, phase_seg1 is added with a delay time or phase_seg2 is subtracted from the advance time to obtain a new phase buffer time for the bit, thereby achieving synchronization.

## 29.3.4 STREAM PROCESS

### 29.3.4.1 Data Buffering

The data cache includes two parts: a transmit buffer and a receive buffer. The data to be sent on the CAN bus is loaded into the buffer area. This buffer area is called the "transmission buffer"; The data received from the CAN bus is also stored in the buffer area, which is called the "receiver buffer". The size of the buffer is 13 bytes, including one-byte frame information, 2 to 4 bytes identifiers (standard or extended frame), and 8 bytes of data.
CPU configures the transmission of the data information (frame information, identification code, data), and then enable the transmit bit. The transmit data information is spliced into a parallel complete data to be transmitted (including the CRC check code) according to the current frame information and stored in transmission buffer. Stream process unit wait for the appropriate time to send data to the bit timing unit.
The received message is placed in the receiving buffer. After receiving, the receiving completion interrupt will be generated. After receiving the interrupt, the CPU will read the data in the receiving buffer and clear the receiving buffer, and STATE [0] will be 0. If the CPU does not read in time, STATE [1] will remain at 1. If a new message is received at this time, overflow will occur and not respond with ack by default.
In new design, there is another independent transmit buffer which has another corresponding transmit request bit. Besides, there is a receive FIFO can be configured to use. Rx data has a RDATA address to be read by host. The size of data is 18 word (one-word frame information, one-word Id, 16-words data) for transmit and 19 word (1-word timestamp additional) for receive. Rx FIFO has 32bits×128 memory space which allow to contain 6 receive message.
Two transmit request bit in CAN_CMD corresponds to two transmit buffers. Transmit message must written to registers before setting transmit request bit. After setting transmit request bit, transmit messages in registers stores in corresponding transmit buffer. When the RKCAN buffer1 transmission frame complete, 'tx_req_1' is automatically cleared to 0.
CAN support RX FIFO. When FIFO enabled, receive data stored in FIFO as Receive FIFO message format shown below. Receive data should read from the RXFIFO entrance. IF FIFO is disabled, receive data stored in RXDATA registers and should read from those registers every time.

| … | … | … | … |
| RX FIFO RB0-DATA15 | 0x0048 | RO | Same as CAN_RXDATA |

### 29.3.4.2 Receive Data

According to the bus protocol, taking the data frame of the extended frame format as an example, the receiving data state machine is as follows:

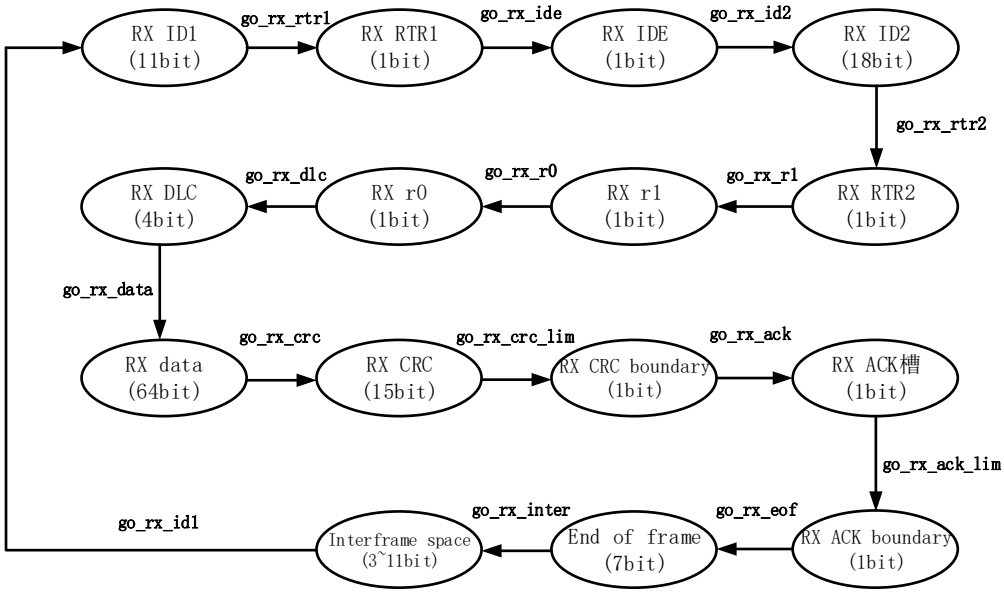

Fig. 29-7 Receive data state diagram

Each state of the state machine corresponds to which "field" of the frame data the receiver is in when receiving data, and only one of all state flags is valid at the same time. The method of implementation is as follows: Define a bit counter, add one to each sample point (provided by the bit timing module). At the same time, according to the current state of the state machine, it is determined in this state that the bit counter needs to count to what value (determined by the length of each field defined in the protocol) to generate a jump signal to the next state transition. Whenever a hopping signal is generated, the counter is cleared and ready to begin counting for the next state.

The receiving state machine ensures that the bus controller can automatically recognize the current receiving state when receiving data. After that, the data of each data field needs to be stored in the corresponding register according to different states, and then the next operation is performed.

### 29.3.4.3 Transmit Data

CAN accesses message element space of a buffer in TX block only if the respective request bit is set. The Host must respect access rules to avoid memory collisions, that is, after the Host sets a buffer ready request through the CMD register, it should not read or write the respective message element space until the respective request bit is in a clear/unset state.

Copyright 2022 © Rockchip Electronics Co., Ltd. 

Parallel data is serially transmitted to the bus according to a specific timing. The sending point is the tx_point. The transmit counter is self-added in the valid data portion of the data frame, and is cleared when one frame of data is transmitted or the bus is in an error state. The implementation is as follows: Combine all the data to be sent into a completely parallel data chain according to the currently set frame type; Using tx_pointer as a data link pointer, obtaining a serial data signal (tx_bit) to be transmitted; Determine what type of data to send according to the current state, and determine the data tx_next to be sent at the next transmission time; Synchronize the data transmission signal tx with the tx_next through the transmission point tx_point to obtain a true transmission signal tx.

#### 29.3.4.4 Bit Stuffing

Bit stuffing is a function set to prevent burst errors. Add a bit of inversion data when the same level lasts 5 bits.

- **Sending unit**

The data between the SOF and CRC segments when transmitting data frames and remote frames. If the same level lasts for 5 bits, the next bit (bit 6) is inserted with the level of the 1st bit and the first 5 bits.

- **Receiving unit**

Data between SOF and CRC segments when receiving data frames and remote frames. If the same level lasts for 5 digits, the next bit (bit 6) needs to be deleted and received. If the 6th bit is the same level as the first 5 bits, it will be treated as an error and an error frame will be sent.

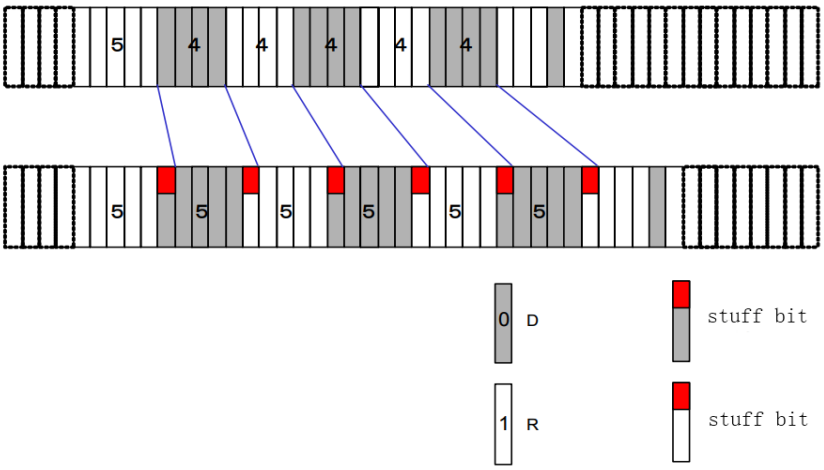

Fig. 29-8 Bit Stuffing

#### 29.3.4.5 Transmit Event FIFO

The Transmit Event FIFO (TEF) allows the application to keep track of the order and time the messages were transmitted. The TEF works similar to a Receive FIFO, which is a 32bits×16 FIFO. Instead of storing received messages, it stores transmitted messages. Messages are only saved if TEF enable is set. The Sequence Number (SEQ) of the transmitted message is copied into the TEF Object. The payload data are not stored. Transmitted messages are timestamped if TEFTSEN is set. Transmit message format store in TXE FIFO as follow:

Copyright 2022 © Rockchip Electronics Co., Ltd.

Table 29-2 TXE FIFO message format

| NAME | Offset | Access | Description |
|---|---|---|---|
| TXE FIFO TB0-INFO | 0x0000 | RO | Same as CAN_TXFRAMEINFO |
| TXE FIFO TB0-ID | 0x0004 | RO | Same as CAN_TXID |
| TXE FIFO TB0-TIMESTAMP | 0x0008 | RO | TX TIMESTAMP VALUE |
| TXE FIFO TB1-INFO | 0x000c | RO | Same as CAN_TXFRAMEINFO |
| TXE FIFO TB1-ID | 0x0010 | RO | Same as CAN_TXID |
| TXE FIFO TB1-TIMESTAMP | 0x0014 | RO | TX TIMESTAMP VALUE |
| … | … | … | … |

#### 29.3.4.6 TIMESTAMP

CAN Controller module contains a Time Base Counter(TBC). The TBC is a 32-bit free-running counter that increments on multiples of CAN clock and rolls over to zero. TBC can be cleared by writing any value to TBC.

- TIMESTAMP_CTRL is used to configure the prescale for the TBC.
- Setting TIMESTAMP_CTRL.TBCEN enables the TBC.
- Clearing TBCEN disables, stops and resets the TBC.
- The TBC has to be disabled before writing to TBC by clearing TBCEN.
- The application can read TBC at any time. Like with any multibyte counter, the application has to consider that the counter increments and might rollover between reading the different bytes of the counter. A rollover of the TBC will generate an interrupt.

Capturing of time stamps at the sample points of the Start of Frame bits of received and transmitted frames.

### 29.3.5 ERROR PROCESS

There are five types of errors. Multiple errors can occur at the same time.

- **BIT ERROR**:

A unit that is sending a bit on the bus also monitors the bus. A BIT ERROR has to be detected at that bit time, when the bit value that is monitored is different form the bit value that is sent. An exception is the sending of a 'recessive' bit during the stuffed bit stream of the ARBITRATION FIELD of during the ACK SLOT. Then no BIT ERROR occurs when a 'dominant' bit is monitored. A TRANSMITTER sending a PASSIVE ERROR FLAG and detecting a 'dominant' bit does not interpret this as a BIT ERROR.

- **BIT STUFF ERROR**:

A STUFF ERROR has to be detected at the bit time of the $6^{th}$ consecutive equal bit level in a message field that should be coded by the method of bit stuffing.

- **FORM ERROR**:

A FORM ERROR has to be detected when a fixed-form bit field contains one or more illegal bits. (Exception is the detection of a dominant bit during the last bit of END OF FRAME by a RECEIVER, or the detection of a dominant bit during the last bit of ERROR DELIMITER or OVERLOAD DELIMITER by any node). FORM-ERROR.

- **ACK ERROR**:

An ACK ERROR has to be detected by a transmitter whenever it does not monitor a 'dominant' bit during the ACK SLOT.

- **CRC ERROR**:

The CRC sequence consists of the result of the CRC calculation by the transmitter. The receivers calculate the CRC in the same way as the transmitter. A CRC ERROR has to be detected, if the calculated result is not the same as that received in the CRC sequence.

## 29.4 Register Description

### 29.4.1 Internal Address Mapping

Slave address can be divided into different length for different usage, which is shown as

follows.

### 29.4.2 Registers Summary

| Name | Offset | Size | Reset Value | Description |
|---|---|---|---|---|
| CAN_MODE | 0x0000 | W | 0x00000000 | Mode Configure Register |
| CAN_CMD | 0x0004 | W | 0x00000000 | Request Command Register |
| CAN_STATE | 0x0008 | W | 0x00000000 | Controller State Register |
| CAN_INT | 0x000C | W | 0x00000000 | Interrupt State Register |
| CAN_INT_MASK | 0x0010 | W | 0x00000000 | Interrupt Mask Registers |
| CAN_DMA_CTRL | 0x0014 | W | 0x00000000 | DMA Mode Control Register |
| CAN_BITTIMING | 0x0018 | W | 0x00000000 | Bit Timing Configure Register. This register work in CAN mode. |
| CAN_ARBITFAIL | 0x0028 | W | 0x00000000 | Arbiter Fail Code Register |

## 29.6 Application Notes

### 29.6.1 Controller initialization flow

The controller must configure the registers after power-up or hardware reset. During the operation of the controller, a software reset request may be sent and reconfigured (re-initialized) as shown below.

After the initialization is completed, the controller enters the working mode, sends the frame to be sent to the buffer, and then sets the "send request" flag of the command register to start transmitting.

*Copyright 2022 © Rockchip Electronics Co., Ltd.* 

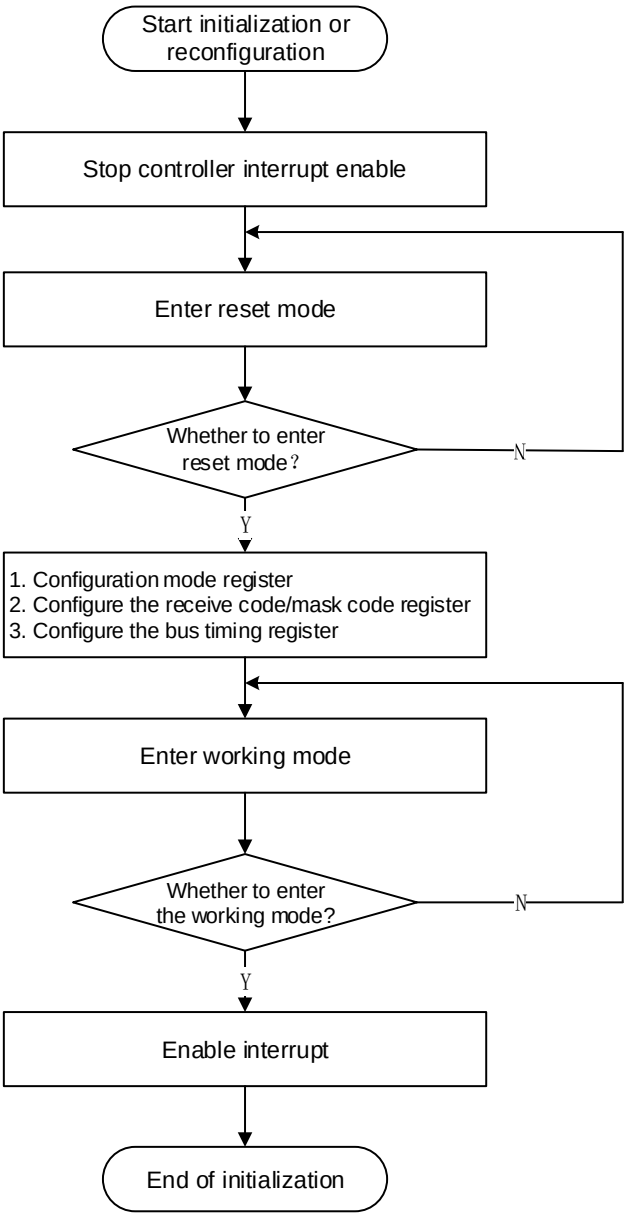

Fig 1-1 CAN Initialization Flow

## 29.6.2 Loop-back Mode

The controller must configure the registers after power-up or hardware reset. During the operation of the controller, a software reset request may be sent and reconfigured (re-initialized) as shown below.

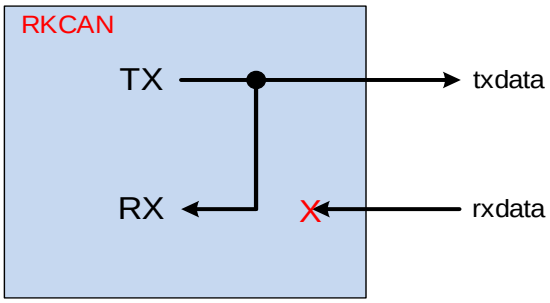

Fig 1-2 Loopback Mode

## 29.6.3 Silent Mode

The controller must configure the registers after power-up or hardware reset. During the operation of the controller, a software reset request may be sent and reconfigured (re-initialized) as shown below.

Copyright 2022 © Rockchip Electronics Co., Ltd.

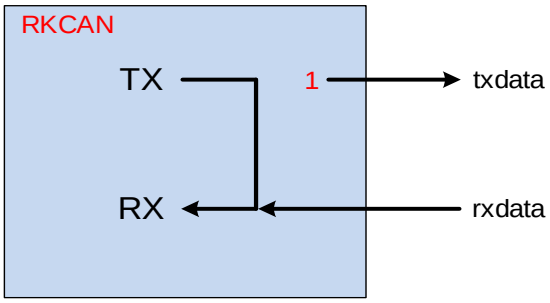

Fig 1-3 Silent Mode

### 29.6.4 Rxstx Mode

- 1'b0: RKCAN cannot receive the data sent by itself;
- 1'b1: RKCAN can receive the data sent by itself, and when the ID of the frame is the same as the ID_CODE of RKCAN itself, RKCAN will store the frame information into CAN_RXDATA1/2.

### 29.6.5 Txorder Mode

The Txorder Mode is used to determine the order in which data is sent.

- 1'b0: Data transmission order is "tx_data1[7:0] --> tx_data1[15:8] --> tx_data1[23:16] --> tx_data1[31:24] -->tx_data2[7:0] --> tx_data2[15:8] --> tx_data2[23:16] --> tx_data2[31:24]";
- 1'b1: Data transmission order is "tx_data2[31:0] --> tx_data1[31:0]".

### 29.6.6 Rxsort Mode

The Rxsort Mode is used to determine how the received data is stored.

- 1'b0: The data received first is placed in the lower address;
- 1'b1: The data received first moves to the upper address, and the data received later is placed at the lower address.

### 29.6.7 Cover Mode

- 1'b0: RKCAN can't receive new frame before receive registers cleared.
- 1'b1: RKCAN can receive new frame before receive registers cleared, and new RXDATA will cover old RXDATA.

### 29.6.8 Overload Mode

According to the CAN protocol, a CAN transceiver will generate an OVERLOAD frame in three cases:

- When the CAN is used as a receiver, if it is necessary to delay the next frame.
- Detection of a dominant bit at the first and second bit of Intermission.
- If an CAN node samples a dominant bit at the eight bits (the last bit) of an ERROR DELIMITER or OVERLOAD DELIMITER.
  1'b0: Overload Lite Mode: RKCAN only generates overload frames in the CASE2.
  1'b1: Overload Extended Mode: RKCAN can generates overload frames in all three cases.

### 29.6.9 Auto Retx Mode

Auto Retransmission Mode.

- 1'b0: Disable. RKCAN return to idle state after transmit DATA/RTR frame failed, and set tx_req to 0.
- 1'b1: Enable. The RKCAN automatically retransmit frames which have lost arbitration or have been disturbed by errors during transmission.

### 29.6.10 Auto Bus On

Auto Bus on Enable.

- 1'b0: After the RKCAN has entered bus_off state, the software can start a bus-off recovery sequence by resetting the work_mode to 0.
- 1'b1: Automatic reset TEC/REC to bus_on after 128 occurrences of 11 consecutive recessive bits have been monitored on the bus.

### 29.6.11 Sleep Mode

The core enters Sleep mode from Configuration or Normal mode when the SLEEP bit is 1 in the CAN_MODE register, the CAN bus is idle, and there are no pending transmission

Copyright 2022 © Rockchip Electronics Co., Ltd.

requests.
The core enters Configuration mode when any configuration condition is satisfied. The core enters Normal mode (clearing the SLEEP request bit in the sleep register and also clearing the corresponding status bit) under the following (wake-up) conditions:

- Whenever the SLEEP bit is set to 0.
- Whenever the SLEEP bit is 1, and bus activity is detected.
- Whenever there is a new message for transmission.

Interrupts are generated when the core enters Sleep mode or wakes up from Sleep mode.

### 29.6.12 DMA Support

The CAN supports DMA signaling with the use of two output signals (dma_tx_mode and dma_rx_mode) to indicate when transmit buffer is empty or when the receive FIFO is full. The controller uses two DMA channels, one for the transmit data and one for the receive data.
DMA transmit and receive support enabled by setting corresponding bit in CAN_DMA_CTRL register. Once enabled whenever both transmit buffer is empty dma_tx_mode is set, DMA should write transmit message. At last CPU set transmit request bit to initiate CAN.

- If RX FIFO is disabled, dma_rx_mode is set when message received successfully, DMA should read RXDATA from receive registers.
- If RX FIFO is enabled, dma_rx_mode is set when message received and FIFO reached watermark，DMA should read RXDATA from Rx FIFO entrance.

# Chapter 30 Flexible Serial Peripheral Interface (FSPI )

## 30.1 Overview

The FSPI is a flexible serial peripheral interface host controller to interface with external device.

The FSPI supports the following features:

- Support various vendor devices with flexible command sequencer engine
  - Serial NOR Flash
  - Serial NAND Flash
  - Serial pSRAM
  - Serial SRAM
- Support SDR mode
- Support Single/Dual/Quad IO mode
- Support a 32-bit AHB slave to read and write controller register bank and initiate command sequence, including transfer data from/to external device indirectly
- Support a 32-bit AHB master with embedded DMA engine to transfer data from/to external device indirectly
- Support independent clock for system bus HCLK and controller core SCLK
- Support maskable interrupts generation
- Support sampling clock with optionally configurable delay line
- Support 2 CS# operation

## 30.2 Block Diagram

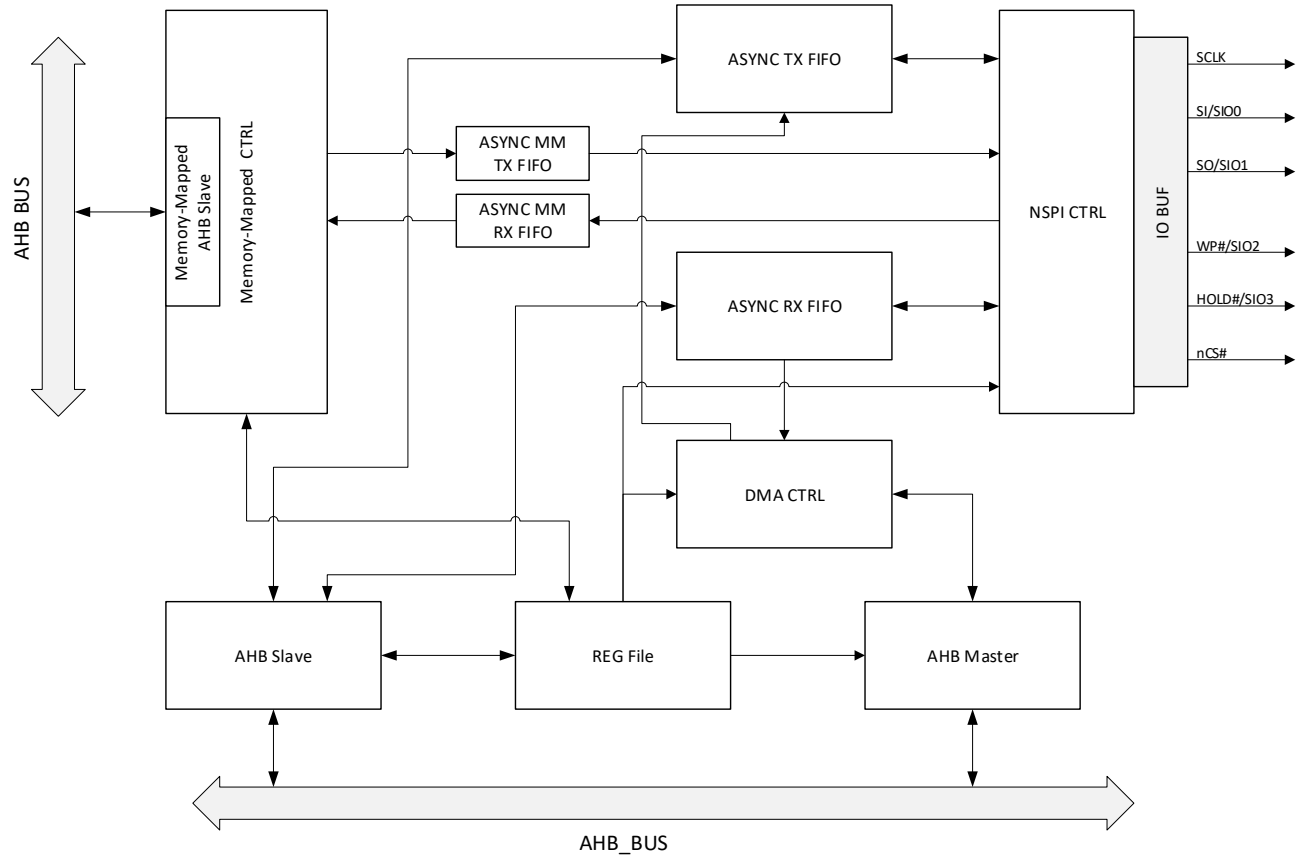

Fig. 30-1 FSPI Architecture

Memory-Mapped AHB slave is available when XIP feature is present. In current chip, this feature is not provided.

## 30.3 Function Description

### 30.3.1 AHB Slave

The AHB slave block is used to configure the register of controller to generate flexible

command sequence, process the interrupt exception, target various device feature and AC timing specification. It is also used to write CMD/ADDR/DATA to TX FIFO and read DATA from RX FIFO which buffer the DATA from external device.

### 30.3.2 AHB Master

When the embedded DMA CTRL is used to transfer DATA, the AHB master is used to transfer data to other system region, such as internal SRAM, peripheral, external DRAM.

### 30.3.3 Memory-Mapped AHB Slave

After the software initialize the controller based on the specialized memory device, CPU and other system bus masters can read data from external memory directly. If the external memory is SRAM or pSRAM, it also supports write data to it. The Memory-Mapped AHB Slave module can generate the relative CS# based on the access address from system address, example CS#0 and CS#1. Non-Supported in this chip.

### 30.3.4 REG File

The REG File is configurable register bank to control the store the static configuration and dynamic status of controller.

### 30.3.5 DMA CTRL

A block takes responsible for splitting a long length transfer trans into AHB bus transaction and interfacing with ASYNC TX or RX FIFO.

### 30.3.6 FIFO

There are four FIFO in the FSPI controller. ASYNC TX FIFO and ASYNC RX FIFO is for normal transaction that initiated by command sequence driver. The ASYNC MM (Memory-Mapped) TX FIFO and ASYNC MM (Memory-Mapped) RX FIFO is only used to buffer DATA from or to external device initiated by system bus master directly.

### 30.3.7 NSPI CTRL

Sequence decode engine which generates specialized timing sequence for various device. The NSPI decode the transaction from TX FIFO and Memory-Mapped Controller and convert it to relative CMD/ADDR/DATA frame based on the configuration.

## 30.4 Register Description

### 30.4.1 Internal Address Mapping

Slave address can be divided into different length for different usage, which is shown as follows.

Table 30-1 FSPI Address Mapping Table

| Name | Address Base | Size |
|---|---|---|
| FSPI CFG | 0xFE2B0000 | 0x10000(64KB) |

### 30.4.2 Registers Summary

# 30.6 Application Notes

## 30.6.1 Typical Program Flow Without DMA

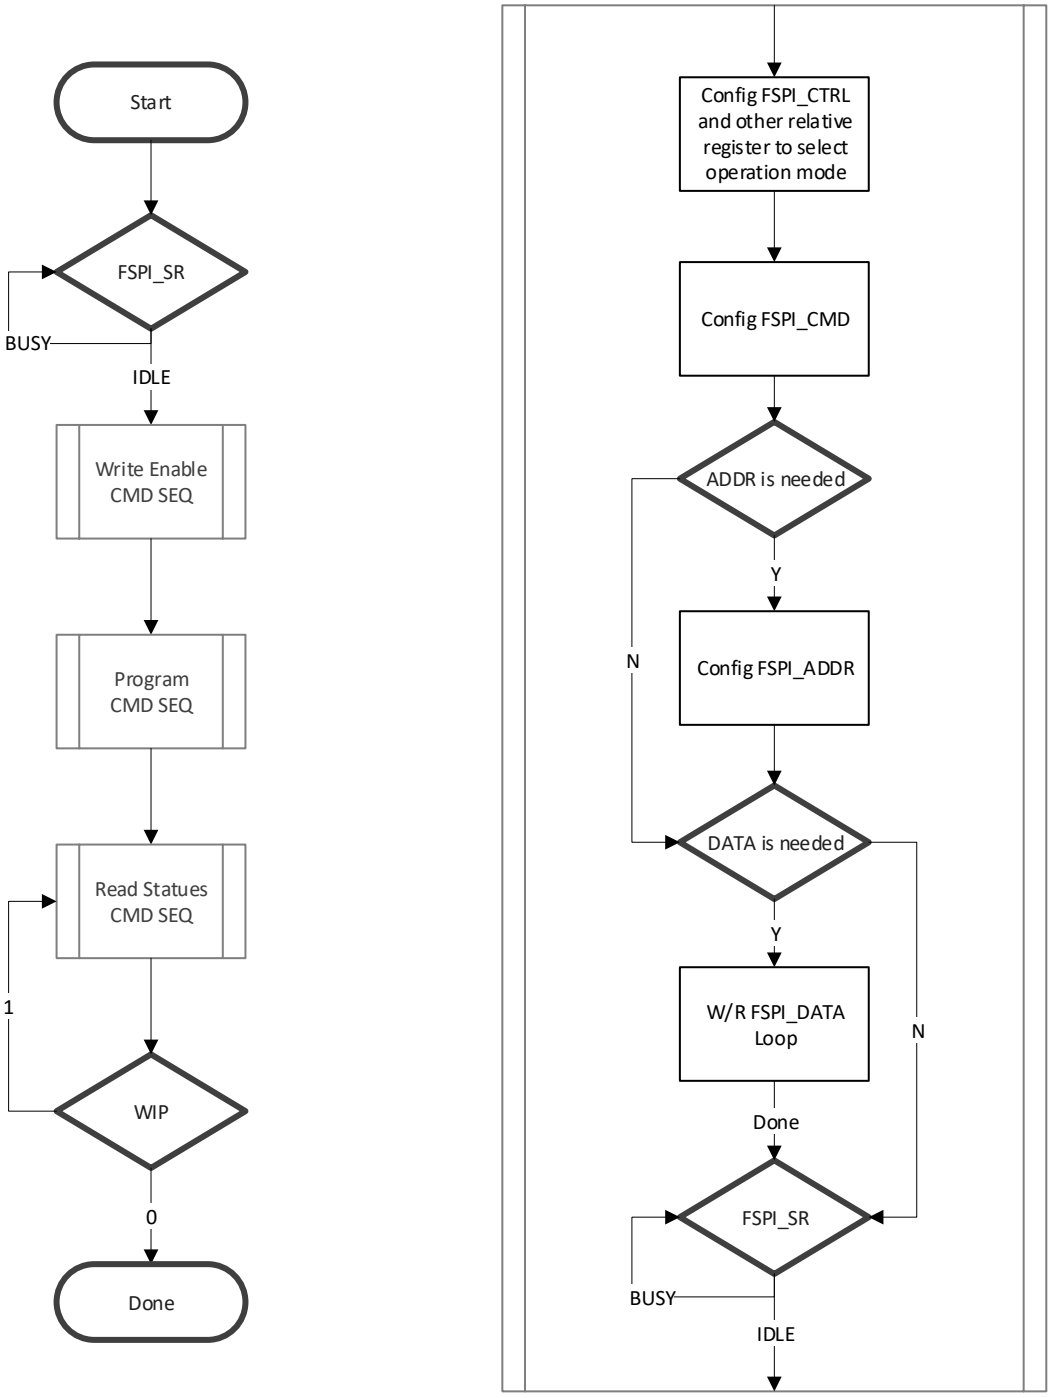

Fig. 30-2 Program Flow

All the AHB bus write data to FSPI_CMD, FSPI_ADDR and FSPI_DATA will be marked with different header and then pushed into transmit FIFO by writing order.

Copyright 2022 © Rockchip Electronics Co., Ltd.

## 30.6.2 Typical READ Flow Without DMA

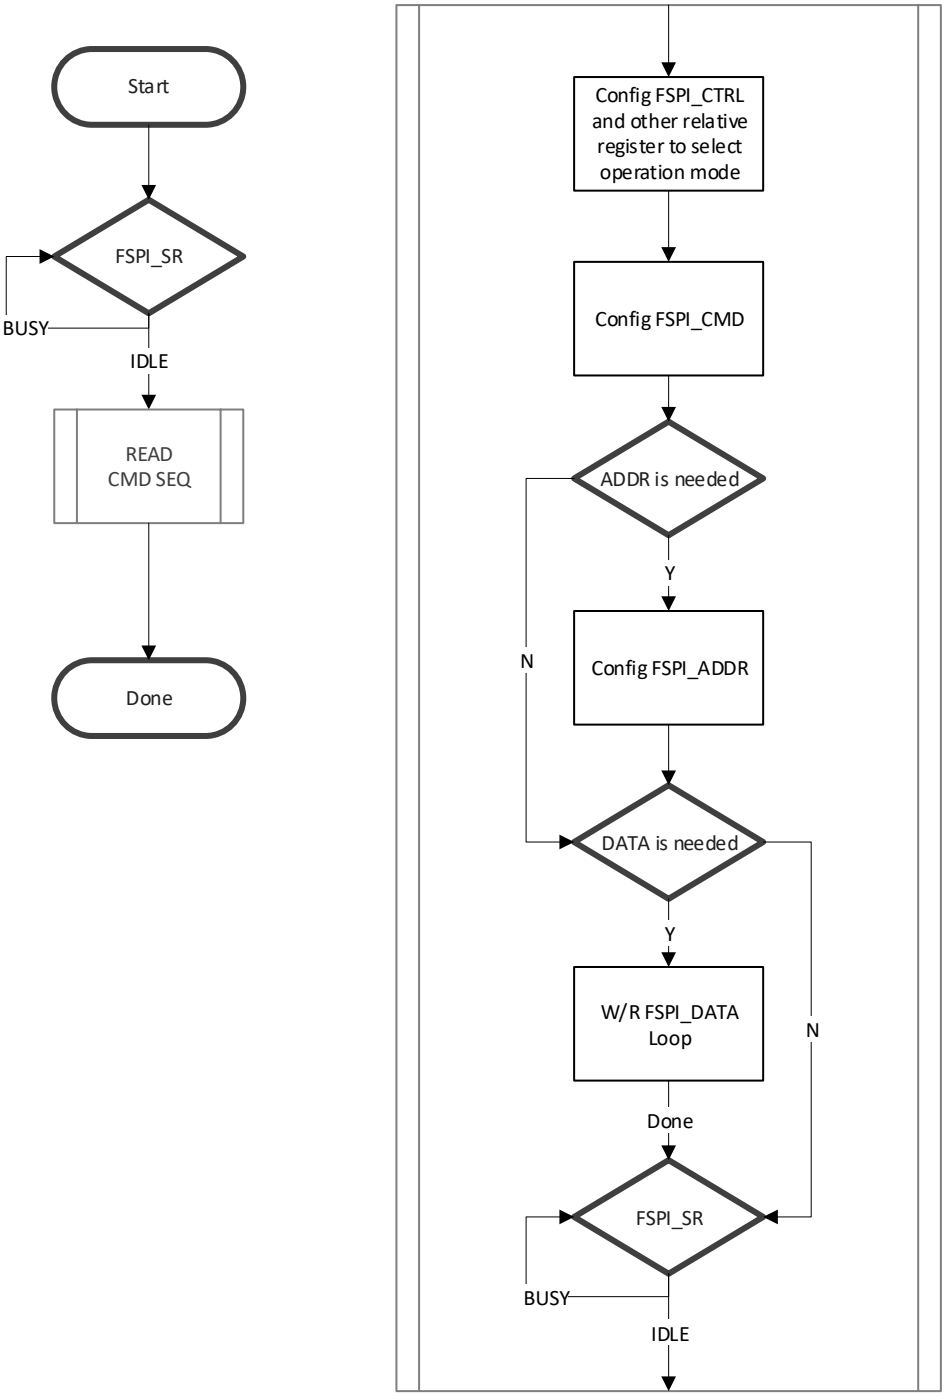

Fig. 30-3 Read Flow

### 30.6.3 Command Flow with DMA

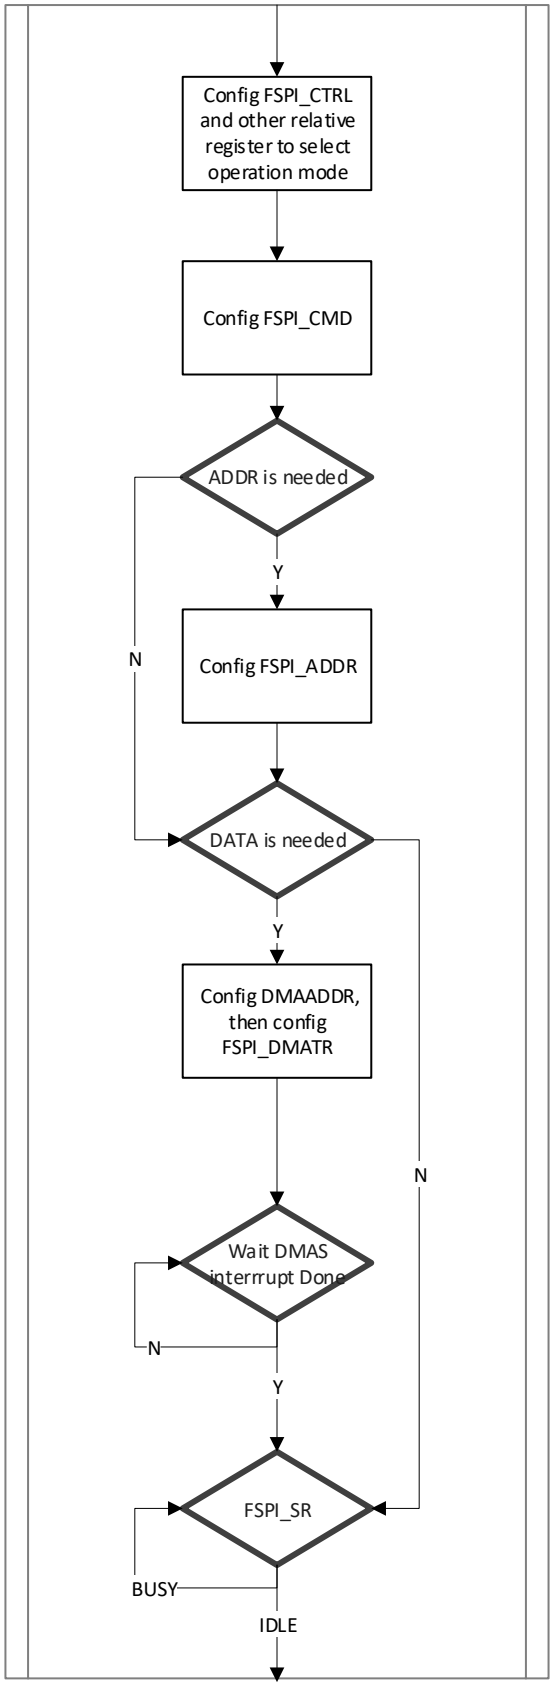

Fig. 30-4 Command with DMA Flow

The total transfer bytes is decided by TRB register in FSPI_CMD and must be aligned to 2 bytes.

Copyright 2022 © Rockchip Electronics Co., Ltd.

### 30.6.4 SPI Mode and Sampling Phase Control

The register SPIM in FSPI_CTRL will decide the default value of SCLK when CS# is inactive. When SPIM=0, the default value is 0, means Mode 0. When SPIM=1, the default value is 1, means SPI Mode 3.

The register SHIFTPAHSE in FSPI_CTRL will decide when to sample the SIO data. If SHIFTPAHSE=0, it will sample the data at the posedge of SCLK sampling clock. If SHIFTPHASE=1, it will sample the data at the negedge of SCLK sampling. The phase delay of sampling clock SCLK is configurable by SMP_DLL_CFG. It is strongly recommended that the SMP_DLL_CFG is set to 1 when SCLK_SMP_SEL is in bypass mode.

Individual FSPI_DLL_CTRL[n] allows flexibly control the DLL for each CSn channel, and the DLL is switched dynamically when the CSn is in operation.

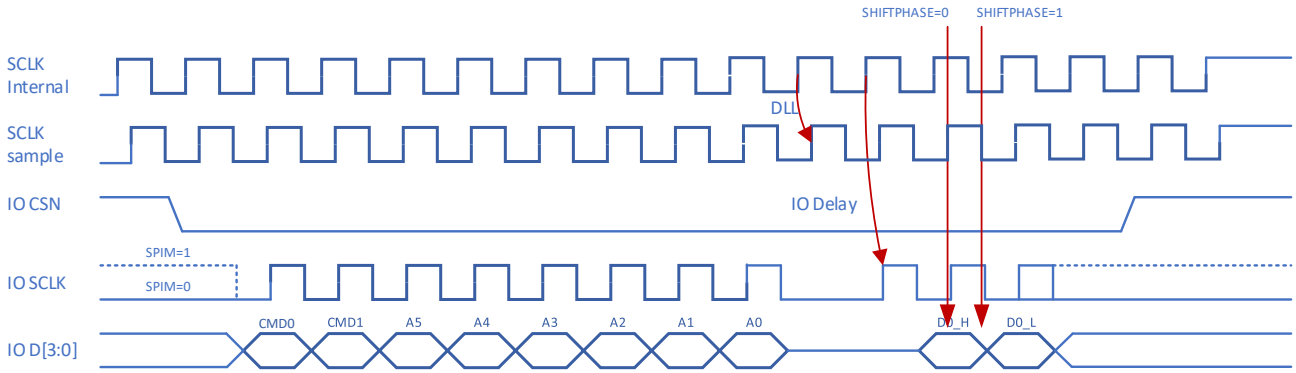

Fig. 30-5 SPI mode

### 30.6.5 Idle Cycles

The FSPI_CTRL register is a global control register, when the controller is in busy state (FSPI_SR), FSPI_CTRL cannot be set. The field IDLE_CYCLE (FSPI_CTRL[7:4]) of this register are used to configure the idle level cycles of FSPI core clock (SCLK) before reading the first bit of the read command.

Like the following picture shows, the highlighted line of the SCLK is the idle cycles, during these cycles, the chip pad is switched to output. When IDLE_CYCLE =0, it means there will be no idle level cycles.

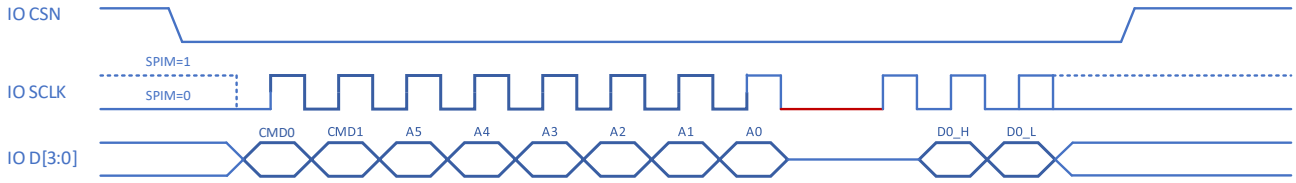

Fig. 30-6 Idle cycles

### 30.6.6 Memory-Mapped Mode

After the Controller is configured as Memory-Mapped mode, the normal operation mode is not allowed which means indirect command transaction is forbidden unless software configures the FSPI_MODE back to indirect access mode.

Before switching into Memory-Mapped mode, the software should initiate some transactions to configure the external device, such as Quad IO enable and IO Drive Strength.

In Memory-Mapped mode, it supports read transaction from serial NOR Flash and serial pSRAM, but only support write transaction into serial pSRAM.

# Chapter 31 Serial Peripheral Interface (SPI)

## 31.1 Overview

The serial peripheral interface is an APB slave device. There are four possible combinations for the serial clock phase and polarity. The clock phase (SCPH) determines whether the serial transfer begins with the falling edge of slave select signals or the first edge of the serial clock. The slave select line is held high when the SPI is idle or disabled. This SPI controller can work as either master or slave mode.

SPI Controller supports the following features:
- Support Motorola SPI, TI Synchronous Serial Protocol and National Semiconductor Micro wire interface
- Support 32-bit APB bus
- Support two internal 16-bit wide and 64-location deep FIFOs, one for transmitting and the other for receiving serial data
- Support two chip select signals in master mode
- Support 4,8,16 bit serial data transfer
- Support configurable interrupt polarity
- Support asynchronous APB bus and SPI clock
- Support master and slave mode
- Support DMA handshake interface and configurable DMA water level
- Support transmit FIFO empty, underflow, receive FIFO full, overflow, interrupt and all interrupts can be masked
- Support configurable water level of transmit FIFO empty and receive FIFO full interrupt
- Support combine interrupt output
- Support up to half of SPI clock frequency transfer in master mode and one quarter of SPI clock frequency transfer in slave mode
- Support full and half duplex mode transfer
- Stop transmitting SCLK if transmit FIFO is empty or receive FIFO is full in master mode
- Support configurable delay from chip select active to SCLK active in master mode
- Support configurable period of chip select inactive between two parallel data in master mode
- Support big and little endian, MSB and LSB first transfer
- Support two 8-bit audio data store together in one 16-bit wide location
- Support sample RXD 0~3 SPI clock cycles later
- Support configurable SCLK polarity and phase
- Support fix and incremental address access to transmit and receive FIFO
- Support timeout mechanism in slave mode
- Support BYPASS slave mode, in which RX and TX logic is drive by SCLK_IN directly instead of spi_clk

## 31.2 Block Diagram

The SPI Controller comprises with:
- AMBA APB interface and DMA Controller Interface
- Transmit and receive FIFO controllers and an FSM controller
- Register block
- Shift control and interrupt

Copyright 2022 © Rockchip Electronics Co., Ltd. 

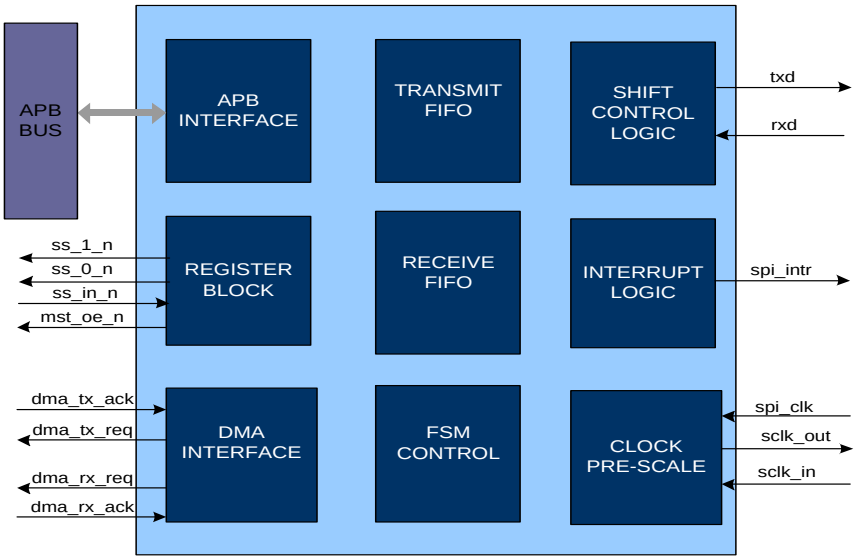

Fig. 31-1 SPI Controller Block Diagram

**APB INTERFACE**

The host processor accesses data, control, and status information on the SPI through the APB interface. The SPI supports APB data bus widths of 32 bits and 8 or 16 bits when reading or writing internal FIFO if data frame size(SPI_CTRL0[1:0]) is set to 8 bits.

**DMA INTERFACE**

This block has a handshaking interface to a DMA Controller to request and control transfers. The APB bus is used to perform the data transfer to or from the DMA Controller.

**FIFO LOGIC**

For transmit and receive transfers, data transmitted from the SPI to the external serial device is written into the transmit FIFO. Data received from the external serial device into the SPI is pushed into the receive FIFO. Both FIFOs are 64x16bits.

**FSM CONTROL**

Control the state's transformation of the design.

**REGISTER BLOCK**

All registers in the SPI are addressed at 32-bit boundaries to remain consistent with the APB bus. Where the physical size of any register is less than 32-bits wide, the upper unused bits of the 32-bit boundary are reserved. Writing to these bits has no effect; reading from these bits returns 0.

**SHIFT CONTROL**

Shift control logic shift the data from the transmit FIFO or to the receive FIFO. This logic automatically right-justifies receive data in the receive FIFO buffer.

**INTERRUPT CONTROL**

The SPI supports combined and individual interrupt requests, each of which can be masked. The combined interrupt request is the OR relationship between all other SPI interrupts after masking.

## 31.3 Function Description

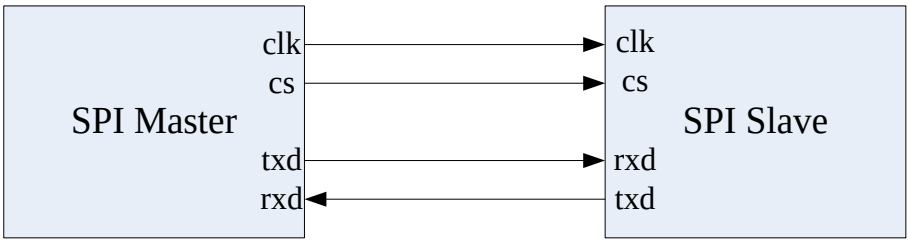

Fig. 31-2 SPI Master and Slave Interconnection

The SPI controller support dynamic switching between master and slave in a system. The diagram show how the SPI controller connects with other SPI devices.

**Operation Modes**

The SPI can be configured in the following two fundamental modes of operation: Master Mode when SPI_CTRLR0 [20] is 1'b0, Slave Mode when SPI_CTRLR0 [20] is 1'b1.

**Transfer Modes**

The SPI operates in the following three modes when transferring data on the serial bus.
1). Transmit and Receive
When SPI_CTRLR0 [19:18] == 2'b00, both transmit and receive logic are valid.
2). Transmit Only
When SPI_CTRLR0 [19:18] == 2'b01, the receive data are invalid and should not be stored in the receive FIFO.
3). Receive Only
When SPI_CTRLR0 [19:18] == 2'b10, the transmit data are invalid.

**Clock Ratios**

A summary of the frequency ratio restrictions between the bit-rate clock (sclk_out/sclk_in) and the SPI peripheral clock (spi_clk) are described as:
When SPI Controller works as master, the $F_{spi_clk}$>= 2 × (maximum $F_{sclk_out}$)
When SPI Controller works as slave, the $F_{spi_clk}$>= 6 × (maximum $F_{sclk_in}$)

With the SPI, the clock polarity (SCPOL) configuration parameter determines whether the inactive state of the serial clock is high or low. To transmit data, both SPI peripherals must have identical serial clock phase (SCPH) and clock polarity (SCPOL) values. The data frame can be 4/8/16 bits in length.

When the configuration parameter SCPH = 0, data transmission begins on the falling edge of the slave select signal. The first data bit is captured by the master and slave peripherals on the first edge of the serial clock; therefore, valid data must be present on the txd and rxd lines prior to the first serial clock edge. The following two figures show a timing diagram for a single SPI data transfer with SCPH = 0. The serial clock is shown for configuration parameters SCPOL = 0 and SCPOL = 1.

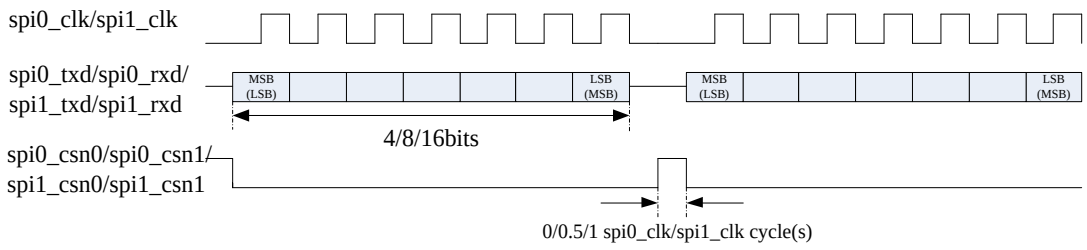

Fig. 31-3 SPI Format (SCPH=0 SCPOL=0)

Copyright 2022 © Rockchip Electronics Co., Ltd.

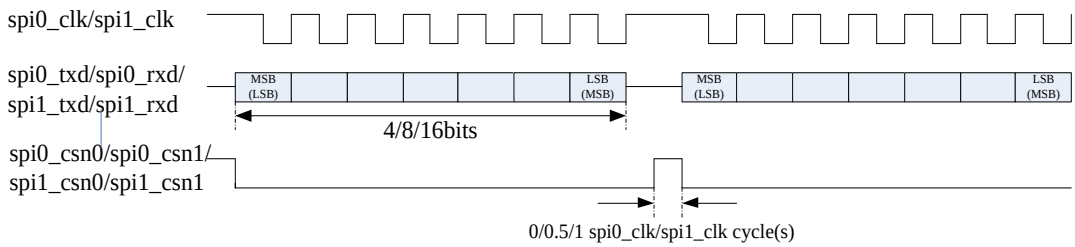

Fig. 31-4 SPI Format (SCPH=0 SCPOL=1)

When the configuration parameter SCPH = 1, both master and slave peripherals begin transmitting data on the first serial clock edge after the slave select line is activated. The first data bit is captured on the second (trailing) serial clock edge. Data are propagated by the master and slave peripherals on the leading edge of the serial clock. During continuous data frame transfers, the slave select line may be held active-low until the last bit of the last frame has been captured. The following two figures show the timing diagram for the SPI format when the configuration parameter SCPH = 1.

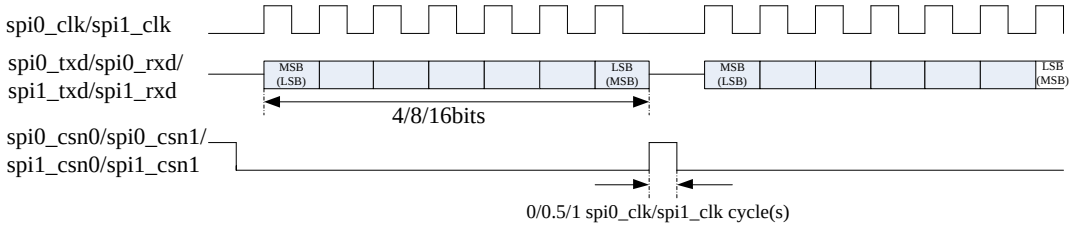

Fig. 31-5 SPI Format (SCPH=1 SCPOL=0)

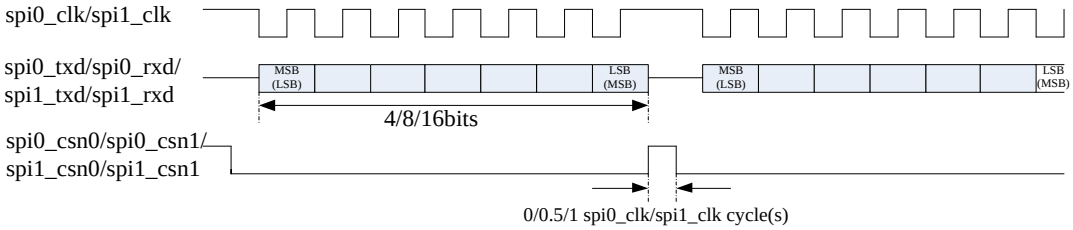

Fig. 31-6 SPI Format (SCPH=1 SCPOL=1)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 15:0 | RW | 0x0000 | baudr<br>SPI Clock Divider. This register is valid only when the SPI is configured as a master device. The LSB for this field is always set to 0 and is unaffected by a write operation, which ensures an even value is held in this register. If the value is 0, the serial output clock (sclk_out) is disabled. The frequency of the sclk_out is derived from the following equation:<br>Fsclk_out = Fspi_clk/ SCKDV<br>Where SCKDV is any even value between 2 and 65534.<br>For example:<br>for Fspi_clk = 3.6864MHz and SCKDV =2<br>Fsclk_out = 3.6864/2= 1.8432MHz |

## 31.6 Application Notes

**Clock Ratios**

A summary of the frequency ratio restrictions between the bit-rate clock (sclk_out/sclk_in) and the SPI peripheral clock (spi_clk) are described as:

When SPI Controller works as master, the Fspi_clk>= 2 × (maximum Fsclk_out)

When SPI Controller works as slave, the Fspi_clk>= 4 × (maximum Fsclk_in)

**Master Transfer Flow**

When configured as a serial-master device, the SPI initiates and controls all serial transfers. The serial bit-rate clock, generated and controlled by the SPI, is driven out on the sclk_out line. When the SPI is disabled (SPI_ENR = 0), no serial transfers can occur and sclk_out is held in "inactive" state, as defined by the serial protocol under which it operates.

*Copyright 2022 © Rockchip Electronics Co., Ltd.* 

**Slave Transfer Flow**

When the SPI is configured as a slave device, all serial transfers are initiated and controlled by the serial bus master.

When the SPI serial slave is selected during configuration, it enables its txd data onto the serial bus. All data transfers to and from the serial slave are regulated on the serial clock line (sclk_in), driven from the serial-master device. Data are propagated from the serial slave on one edge of the serial clock line and sampled on the opposite edge.

# Chapter 32 SPINLOCK

## 32.1 Overview

The hardware spinlock used for spinlock status storage. All the CPU can access spinlock to get the lock status.

## 32.2 Block Diagram

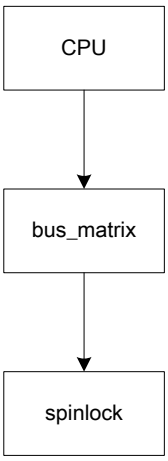

Fig. 32-1 Spinlock in System

## 32.3 Register Description

### 32.3.1 Internal Address Mapping

Slave address can be divided into different length for different usage, which is shown as follows.

### 32.3.2 Registers Summary

| Name | Offset | Size | Reset Value | Description |
|---|---|---|---|---|
| SPINLOCK_STATUS_N (range of n is 0~63) | 0x0+4*n | W | 0x00000000 | spinlock status controller register_n |

*Notes:Size:**B**- Byte (8 bits) access, **HW**- Half WORD (16 bits) access, **W**-WORD (32 bits) access*

### 32.3.3 Detail Register Description

**SPINLOCK_STATUS_N**

Address: Operational Base + offset (0x0000+4*n)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:4 | RO | 0x000000 | reserved |
| 3:0 | RW | 0x0 | spinlock_status<br>when 4bits is 0, 4bits can be written with new value.<br>when 4bits is not 0, 4bits cannot be written.<br>when write data is 0x0000, 4bits clean to 0. |

# Chapter 33 KEYLAD

## 33.1 Overview

KEYLAD is used to securely protect the transmission and operation of the KEY and ensure that other masters cannot access the KEY.
The KEYLAD supports following features:

- Support Link List Item (LLI) DMA transfer
- Support AES-128, AES-192, AES-256 encrypt & decrypt cipher
- Support DES & TDES cipher
- Support AES ECB/CBC/OFB/CFB mode
- Support SM4 ECB/CBC/OFB/CFB mode
- Support DES/TDES ECB/CBC/OFB/CFB mode
- Support for caching OTP or TRNG specific data and deriving it
- Support writing KEY Table data to some specific modules
- Support AES/SM4/DES/TDES lockstep error monitoring

## 33.2 Block Diagram

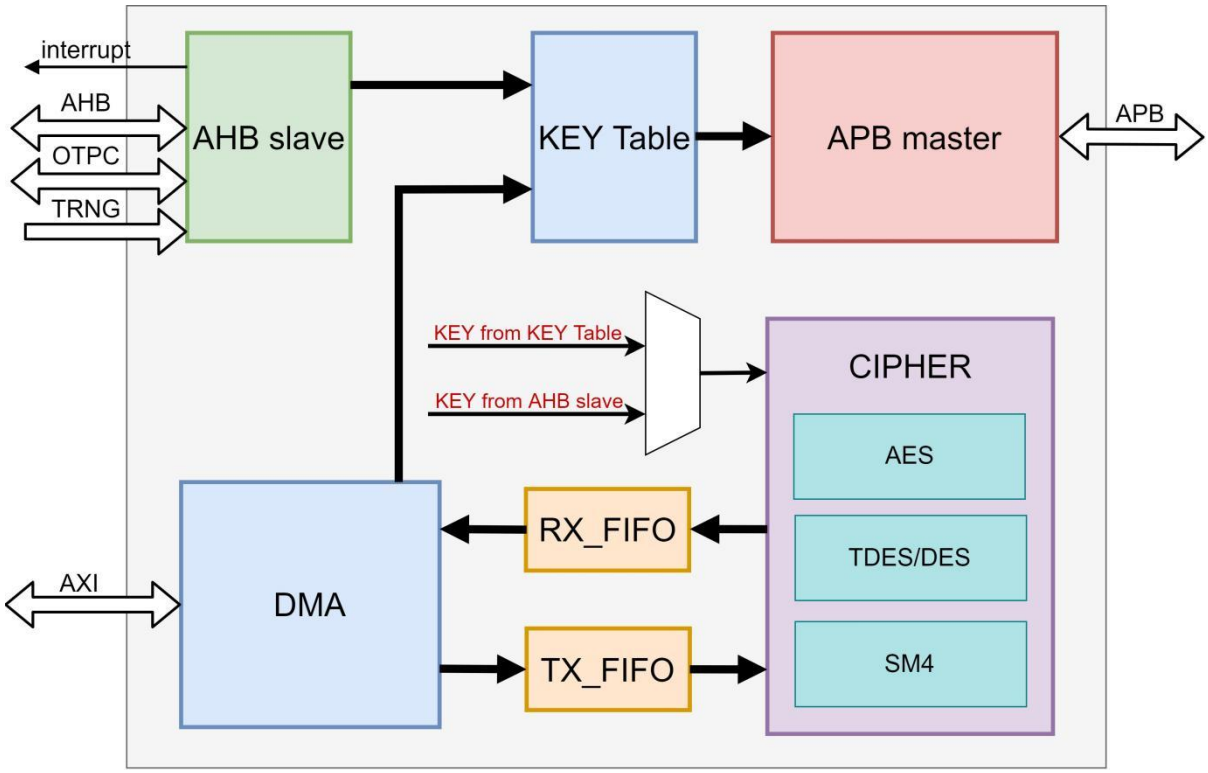

Fig. 33-1 KEYLAD Architecture

KEYLAD contains several modules: AHB_Slave, DMA, CIPHER, Key_table, APB_master.

**AHB_Slave**
AHB_Slave is used to configure registers. This module is in HCLK domain.

**DMA**
DMA is used to transfer data from external memory to RX_FIFO, or from TX_FIFO to KEY Table. DMA uses 64-bits AXI3 protocol with max burst length to 16. LLI transfer is also supported for performance and convenience consideration. This module is in ACLK domain.

**CIPHER**
CIPHER contains AES, SM4, DES/TDES engines. And it also supports various mode operations. The source data is either from RX_FIFO, or from other engine output. The result

Copyright 2022 © Rockchip Electronics Co., Ltd.

data is sending to TX_FIFO. This module is in CLK_CORE domain.

**KEY_Table**
The KEY table is used to store OTP KEY, TRNG data and CIPHER calculate result. KEY table's content can't be see by CPU. This module is in ACLK domain.

**APB_master**
APB_master is used to write data to module configurations that require secret configuration data. This APB_master is write-only APB master. This module is in PCLK domain.

# 33.3 Function Description

## 33.3.1 KEY Table

The KEY Table consists of 32 registers. The 32 word registers are numbered 0~31 one by one.

- Copy data into KEY Table

KEYLAD can copy 8 words OTP KEY or TRNG data to the KEY Table at one time. To copy data to KEY Table, the following steps should be followed:

1. Clear KEYLAD_SRC_NUM_DONE register;
2. Configure the KEYLAD_SRC_NUM_SEL register to select data source;
3. Configure OTPC or TRNG_S to generate data source for KEYLAD;
4. Waiting for KEYLAD_SRC_NUM_DONE register to set;
5. Configure the KEYLAD_OTP_COPY register to copy the data to the specified location in the KEY Table;
6. Waiting for KEYLAD_OTP_COPY register to clear indicates that data is written to KEY Table

- Internal data copy

KEYLAD can also copy the key table data internally, 8 words at a time, by configuring the KEYLAD_INTER_COPY register.

- Copy the KEY Table data to a specific module

KEYLAD has a set of write only APB interfaces, which can write the data in the KEY Table to SCRYPTO, SCRYAMBLE_KEY and HDCP_KEY, one word at a time. To write the data in the KEY Table to a specific module, the following steps should be followed:

1. Configure the KEYLAD_APB_PADDR register to select the destination address;
2. Configure KEYLAD_APB_PWDATA register to select word data corresponding to KEY Table;
3. Configure KEYLAD_APB_CMD register to start data writing;
4. Wait for the KEYLAD_APB_CMD register to clear, indicating that the data has been written to the destination.

## 33.3.2 KEY derivation

KEYLAD can derive the KEY in the KEY Table. If you need to use the data in the KEY Table as the KEY of the operation, you need to configure register KEYLAD_KEY_SEL.

# 33.4 Register Description

## 33.4.1 Internal Address Mapping

Slave address can be divided into different length for different usage, which is shown as follows.

## 33.4.2 Registers Summary

| Name | Offset | Size | Reset Value | Description |
|---|---|---|---|---|
| KEYLAD_CLK_CTL | 0x0000 | W | 0x00000001 | Clock Control Register |
| KEYLAD_RST_CTL | 0x0004 | W | 0x00000000 | Reset Control Register |
| KEYLAD_DMA_INT_EN | 0x0008 | W | 0x00000000 | DMA Interrupt Enable Register |
| KEYLAD_DMA_INT_ST | 0x000C | W | 0x00000000 | DMA Interrupt Status Register |

*Notes:Size:**B**- Byte (8 bits) access, **HW**- Half WORD (16 bits) access, **W**-WORD (32 bits) access, **DW**-Double WORD (64 bits) access*

### 33.4.3 Detail Registers Description

**KEYLAD_CLK_CTL**

Address: Operational Base + offset (0x0000)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:17 | RO | 0x0000 | reserved |
| 16 | WO | 0x0 | write_enable<br>Write enable for lower 16bits, each bit is individual<br>1'b0: Write access disable<br>1'b1: Write access enable |
| 15:1 | RO | 0x0000 | reserved |
| 0 | RW | 0x1 | auto_clkgate_en<br>KEYLAD will gate unused Block Cipher module automatically<br>1'b0: Disable<br>1'b1: Enable |

**KEYLAD_RST_CTL**

Address: Operational Base + offset (0x0004)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:19 | RO | 0x0000 | reserved |
| 18:16 | RW | 0x0 | write_enable<br>Write enable for lower 16bits, each bit is individual<br>1'b0: Write access disable<br>1'b1: Write access enable |
| 15:2 | RO | 0x0000 | reserved |
| 1 | R/WSC | 0x0 | sw_rng_reset<br>Software set this bit to start a reset to TRNG module. After the reset is done, KEYLAD will clear this bit. |
| 0 | R/WSC | 0x0 | sw_cc_reset<br>Software set this bit to start a reset to Symmetric Cipher module. After the reset is done, KEYLAD will clear this bit. |

**KEYLAD_DMA_INT_EN**

Address: Operational Base + offset (0x0008)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:8 | RO | 0x000000 | reserved |
| 7 | RW | 0x0 | lockstep_int_en<br>1'b0: Disable<br>1'b1: Enable |
| 6 | RW | 0x0 | zero_len_int_en<br>1'b0: Disable<br>1'b1: Enable |
| 5 | RW | 0x0 | list_err_int_en<br>1'b0: Disable<br>1'b1: Enable |
| 4 | RW | 0x0 | src_err_int_en<br>1'b0: Disable<br>1'b1: Enable |
| 3 | RW | 0x0 | dst_err_int_en<br>1'b0: Disable<br>1'b1: Enable |
| 2 | RW | 0x0 | src_item_done_int_en<br>1'b0: Disable<br>1'b1: Enable |
| 1 | RW | 0x0 | dst_item_done_int_en<br>1'b0: Disable<br>1'b1: Enable |

*Copyright 2022 © Rockchip Electronics Co., Ltd.*

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 0 | RW | 0x0 | list_done_int_en<br>1'b0: Disable<br>1'b1: Enable |

**KEYLAD_DMA_INT_ST**

Address: Operational Base + offset (0x000C)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:8 | RO | 0x000000 | reserved |
| 7 | RW | 0x0 | lockstep_flag<br>1'b0: Nothing<br>1'b1: Indicate that KEYLAD was attacked |
| 6 | W1C | 0x0 | zero_len<br>1'b0: Nothing<br>1'b1: Indicate that DMA has met an 0 byte source transfer length in list descriptors. After the bit is read, the application should write 1 to clear this bit for next time use |
| 5 | RW | 0x0 | list_err<br>1'b0: Nothing<br>1'b1: Indicate that DMA has met an error response when transfer list descriptors. The state machine will exit current transfer and then return to IDLE state. After the bit is read, the application should write 1 to clear this bit for next time use |
| 4 | W1C | 0x0 | src_err<br>1'b0: Nothing<br>1'b1: Indicate that DMA has met an error response when transfer source data. The state machine will exit current transfer and then return to IDLE state. After the bit is read, the application should write 1 to clear this bit for next time use |
| 3 | W1C | 0x0 | dst_err<br>1'b0: Nothing<br>1'b1: Indicate that DMA has met an error response when transfer destination data. The state machine will exit current transfer and then return to IDLE state. After the bit is read, the application should write 1 to clear this bit for next time use |
| 2 | W1C | 0x0 | src_item_done<br>1'b0: Nothing<br>1'b1: Indicate that DMA has completed a read transfers which the current list descriptor pointed to. After the bit is read, the application should write 1 to clear this bit for next time use |
| 1 | W1C | 0x0 | dst_item_done<br>1'b0: Nothing<br>1'b1: Indicate that DMA has completed a write transfers which the current list descriptor pointed to. After the bit is read, the application should write 1 to clear this bit for next time use |
| 0 | W1C | 0x0 | list_done<br>1'b0: Nothing<br>1'b1: Indicate that DMA has completed all the transfers which the list descriptors pointed to. After the bit is read, the application should write 1 to clear this bit for next time use |

**KEYLAD_DMA_CTL**

Address: Operational Base + offset (0x0010)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:18 | RO | 0x0000 | reserved |

*Copyright 2022 © Rockchip Electronics Co., Ltd.*

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 17:16 | WO | 0x0 | write_enable<br>Write enable for lower 16bits, each bit is individual<br>1'b0: Write access disable<br>1'b1: Write access enable |
| 15:2 | RO | 0x0000 | reserved |
| 1 | R/WSC | 0x0 | dma_restart<br>If DMA data for next stage is not ready, application could pause DMA by descriptor commands. DMA will stop prefetching next descriptor. The application could restart DMA by asserting this bit when DMA data for next state is ready. KEYLAD will continue with previous transfer, and clear the bit automatically. |
| 0 | R/WSC | 0x0 | dma_start<br>DMA asserts the bit to start DMA transfer, then KEYLAD will clear the bit automatically. |

**KEYLAD_DMA_LLI_ADDR**

Address: Operational Base + offset (0x0014)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:0 | RW | 0x00000000 | dma_lli_addr<br>When DMA_CTL start asserted, KEYLAD will read the address to get the 1'st descriptor. It should be 8-bytes align. We suggest dma_lli_addr 64-byte align for best performance consideration. |

**KEYLAD_DMA_ST**

Address: Operational Base + offset (0x0018)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:1 | RO | 0x00000000 | reserved |
| 0 | RO | 0x0 | dma_busy<br>1'b0: DMA idle<br>1'b1: DMA busy |

**KEYLAD_DMA_STATE**

Address: Operational Base + offset (0x001C)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:6 | RO | 0x0000000 | reserved |
| 5:4 | RO | 0x0 | dma_lli_state<br>For debug use only<br>2'b00: IDLE STATE<br>2'b01: FETCH STATE<br>2'b10: WORK STATE<br>Others: Reserved |
| 3:2 | RO | 0x0 | dma_src_state<br>For debug use only<br>2'b00: IDLE STATE<br>2'b01: LOAD STATE<br>2'b10: WORK STATE<br>Others: Reserved |
| 1:0 | RO | 0x0 | dma_dst_state<br>For debug use only<br>2'b00: IDLE STATE<br>2'b01: LOAD STATE<br>2'b10: WORK STATE<br>Others: Reserved |

**KEYLAD_DMA_LLI_RADDR**

*Copyright 2022 © Rockchip Electronics Co., Ltd.*

Address: Operational Base + offset (0x0020)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:0 | RO | 0x00000000 | dma_lli_raddr<br>For debug use only<br>It indicates the current DMA LLI read address |

**KEYLAD_DMA_SRC_RADDR**

Address: Operational Base + offset (0x0024)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:0 | RO | 0x00000000 | dma_src_raddr<br>For debug use only<br>It indicates the current DMA source read address |

**KEYLAD_DMA_DST_WADDR**

Address: Operational Base + offset (0x0028)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:0 | RO | 0x00000000 | dma_dst_waddr<br>For debug use only<br>It indicates the current DMA destination write address |

**KEYLAD_DMA_ITEM_ID**

Address: Operational Base + offset (0x002C)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:8 | RO | 0x000000 | reserved |
| 7:0 | RO | 0x00 | dma_item_id<br>For debug use only<br>It indicates the current descriptor ID |

**KEYLAD_FIFO_CTL**

Address: Operational Base + offset (0x0040)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:18 | RO | 0x0000 | reserved |
| 17:16 | WO | 0x0 | write_enable<br>Write enable for lower 16bits, each bit is individual<br>1’b0: Write access disable<br>1’b1: Write access enable |

## 33.5 Application Note

- KEYLAD lockstep function refers to “Chapter CRYPTO”.
- The cipher function configuration of KEYLAD refers to “Chapter CRYPTO”.
- When performing KEY derivation, you need to configure the dout_byteswap bit segment of KEYLAD_FIFO_CTL to '0'.
- When KEYLAD copies the data in KEY Table to SCRYPTO, the base address of SCRYPTO shall be regarded as 0xfe420000.

# Chapter 34 Share Memory

## 34.1 Overview

The Share Memory is a general memory module which can be accessed by several masters at the same time. And it can be programmed through the APB Slave interface.
The Share Memory supports the following features:

- Support four AXI Slave interfaces with 256 bits data bus width
- Support total 1024KB memory comprised of four memory blocks
- Support shut down and deep sleep mode for each memory block
- Support auto clock gating
- Support weighted Round-Robin arbiter
- Support APB Slave interface for software configuration and status query

## 34.2 Block Diagram

The following figure shows the block diagram of Share Memory.

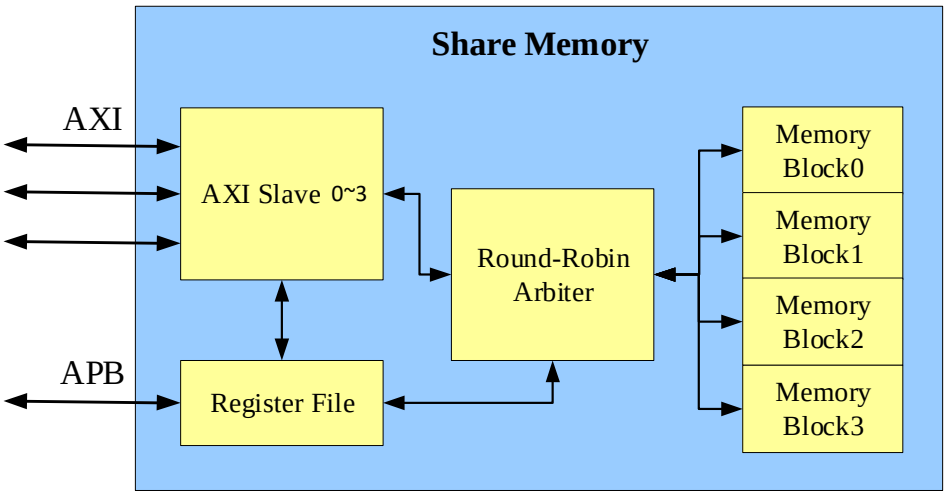

Fig. 34-1 Block Diagram of Share Memory

## 34.3 Function Description

### 34.3.1 Memory Access

There are four memory blocks, and each 256KB block consists of four SRAM banks. That is, the valid address range of the Share Memory is 0xFF000000~0xFF0FFFFF, and the base address of the Memory Block0~3 is 0xFF000000/0xFF040000/0xFF080000/0xFF0C0000.

### 34.3.2 Round-Robin Arbiter

In order to program the priority attribute for every AXI Slave interface, you should configure the following registers of the internal Round-Robin arbiter: SHAREMEM_RRA_SLT, SHAREMEM_RRA_WEIGHT, and SHAREMEM_RRA_SLT_PRI, and then enable the configuration by writing 1 to SHAREMEM_CTRL.cfg_load_en.

## 34.4 Register Description

This section describes the control/status registers of the design. Software should read and write these registers using 32-bits accesses.

| Name | Offset | Size | Reset Value | Description |
|---|---|---|---|---|
| SHAREMEM_RRA_SLT | 0x0000 | W | 0x76543210 | RRA slot assignment register |
| SHAREMEM_RRA_WEIGHT | 0x0008 | W | 0x00000000 | RRA arbitration weight register |
| SHAREMEM_RRA_SLT_PRI | 0x0010 | W | 0x00000000 | RRA slot priority register |
| SHAREMEM_CTRL | 0x0020 | W | 0x00000000 | Global control register |
| SHAREMEM_STATUS | 0x0024 | W | 0x00000000 | Status register |

Copyright 2022 © Rockchip Electronics Co., Ltd.

*Notes: Size: **B**- Byte (8 bits) access, **HW**- Half WORD (16 bits) access, **W**-WORD (32 bits) access*

# 34.5 Application Notes

## 34.5.1 Power Control Flow

Share Memory supports shutdown and deep sleep mode for each memory block, which can be controlled by software.

**1. Enter Shut Down Mode Flow:**

(1) Select shut down mode for specified memory block:

Set PMU_SUBMEM_PWR_GATE_SFTCON0 bit[0] to 1 for block 0
Set PMU_SUBMEM_PWR_GATE_SFTCON0 bit[1] to 1 for block 1
Set PMU_SUBMEM_PWR_GATE_SFTCON0 bit[2] to 1 for block 2
Set PMU_SUBMEM_PWR_GATE_SFTCON0 bit[3] to 1 for block 3

(2) Enable shut down mode for specified memory block:

Set PMU_SUBMEM_PWR_GATE_SFTCON0 bit[8] to 1 for block 0
Set PMU_SUBMEM_PWR_GATE_SFTCON0 bit[9] to 1 for block 1
Set PMU_SUBMEM_PWR_GATE_SFTCON0 bit[10] to 1 for block 2
Set PMU_SUBMEM_PWR_GATE_SFTCON0 bit[11] to 1 for block 3

(3) Check memory power state:

Query until PMU_SUBMEM_PWR_GATE_STS bit[0] equals to 1, to make sure block 0 enters shut down mode
Query until PMU_SUBMEM_PWR_GATE_STS bit[1] equals to 1, to make sure block 1 enters shut down mode
Query until PMU_SUBMEM_PWR_GATE_STS bit[2] equals to 1, to make sure block 2 enters shut down mode
Query until PMU_SUBMEM_PWR_GATE_STS bit[3] equals to 1, to make sure block 3 enters shut down mode

**2. Exit Shut Down Mode Flow:**

(1) Disable shut down mode for specified memory block:

Set PMU_SUBMEM_PWR_GATE_SFTCON0 bit[8] to 0 for block 0
Set PMU_SUBMEM_PWR_GATE_SFTCON0 bit[9] to 0 for block 1
Set PMU_SUBMEM_PWR_GATE_SFTCON0 bit[10] to 0 for block 2
Set PMU_SUBMEM_PWR_GATE_SFTCON0 bit[11] to 0 for block 3

(2) Deselect shut down mode for specified memory block:

Set PMU_SUBMEM_PWR_GATE_SFTCON0 bit[0] to 0 for block 0
Set PMU_SUBMEM_PWR_GATE_SFTCON0 bit[1] to 0 for block 1
Set PMU_SUBMEM_PWR_GATE_SFTCON0 bit[2] to 0 for block 2
Set PMU_SUBMEM_PWR_GATE_SFTCON0 bit[3] to 0 for block 3

(3) Check memory power state:

Query until PMU_SUBMEM_PWR_GATE_STS bit[0] equals to 0, to make sure block 0 exits

Copyright 2022 © Rockchip Electronics Co., Ltd.

shut down mode
Query until PMU_SUBMEM_PWR_GATE_STS bit[1] equals to 0, to make sure block 1 exits shut down mode
Query until PMU_SUBMEM_PWR_GATE_STS bit[2] equals to 0, to make sure block 2 exits shut down mode
Query until PMU_SUBMEM_PWR_GATE_STS bit[3] equals to 0, to make sure block 3 exits shut down mode

**3. Enter Deep Sleep Mode Flow:**

(1) Select deep sleep mode for specified memory block:
Set PMU_SUBMEM_PWR_GATE_SFTCON0 bit[4] to 1 for block 0
Set PMU_SUBMEM_PWR_GATE_SFTCON0 bit[5] to 1 for block 1
Set PMU_SUBMEM_PWR_GATE_SFTCON0 bit[6] to 1 for block 2
Set PMU_SUBMEM_PWR_GATE_SFTCON0 bit[7] to 1 for block 3

(2) Enable deep sleep mode for specified memory block:
Set PMU_SUBMEM_PWR_GATE_SFTCON0 bit[12] to 1 for block 0
Set PMU_SUBMEM_PWR_GATE_SFTCON0 bit[13] to 1 for block 1
Set PMU_SUBMEM_PWR_GATE_SFTCON0 bit[14] to 1 for block 2
Set PMU_SUBMEM_PWR_GATE_SFTCON0 bit[15] to 1 for block 3

(3) Check memory power state:
Query until PMU_SUBMEM_PWR_GATE_STS bit[0] equals to 1, to make sure block 0 enters deep sleep mode
Query until PMU_SUBMEM_PWR_GATE_STS bit[1] equals to 1, to make sure block 1 enters deep sleep mode
Query until PMU_SUBMEM_PWR_GATE_STS bit[2] equals to 1, to make sure block 2 enters deep sleep mode
Query until PMU_SUBMEM_PWR_GATE_STS bit[3] equals to 1, to make sure block 3 enters deep sleep mode

**4. Exit Deep Sleep Mode Flow:**

(1) Disable deep sleep mode for specified memory block:
Set PMU_SUBMEM_PWR_GATE_SFTCON0 bit[12] to 0 for block 0
Set PMU_SUBMEM_PWR_GATE_SFTCON0 bit[13] to 0 for block 1
Set PMU_SUBMEM_PWR_GATE_SFTCON0 bit[14] to 0 for block 2
Set PMU_SUBMEM_PWR_GATE_SFTCON0 bit[15] to 0 for block 3

(2) Deselect deep sleep mode for specified memory block:
Set PMU_SUBMEM_PWR_GATE_SFTCON0 bit[4] to 0 for block 0
Set PMU_SUBMEM_PWR_GATE_SFTCON0 bit[5] to 0 for block 1
Set PMU_SUBMEM_PWR_GATE_SFTCON0 bit[6] to 0 for block 2
Set PMU_SUBMEM_PWR_GATE_SFTCON0 bit[7] to 0 for block 3

(3) Check memory power state:
Query until PMU_SUBMEM_PWR_GATE_STS bit[0] equals to 0, to make sure block 0 exits deep sleep mode
Query until PMU_SUBMEM_PWR_GATE_STS bit[1] equals to 0, to make sure block 1 exits deep sleep mode
Query until PMU_SUBMEM_PWR_GATE_STS bit[2] equals to 0, to make sure block 2 exits deep sleep mode
Query until PMU_SUBMEM_PWR_GATE_STS bit[3] equals to 0, to make sure block 3 exits deep sleep mode

## 34.5.2 Other Notes

- If SHAREMEM_CTRL.addr_round_en is set to 1, you can access the Share Memory using out-of-bounds address such as 0xFF100000~0xFF1FFFFF as the mirror address of 0xFF000000~0xFF0FFFFF, and there is no error response.
- If SHAREMEM_CTRL.addr_round_en is set to 0, when the read or write address exceeds the address boundary, the AXI bus will respond a read or write error. You can read the response status from the register SHAREMEM_STATUS.
- If configure SHAREMEM_CTRL.free_run_mode to 1, internal auto clock gating will be

*Copyright 2022 © Rockchip Electronics Co., Ltd.* 

turned off.

- The programmable slot0 always has the highest priority in the Memory Block0, which is mentioned as the RRA priority region 0.
- The register bit SHAREMEM_CTRL.cfg_load_en is auto clear, so the readvalue is always 0.

*Copyright 2022 © Rockchip Electronics Co., Ltd.* 

# Chapter 35 DECOM

## 35.1 Overview

DECOM can decompress compressed files in GZIP, LZ4, DEFALTE and ZLIB formats. DECOM controller supports the following features:

- Support for decompressing GZIP files
- Support for decompressing LZ4 files, including the General Structure of LZ4 Frame format and the Legacy Frame format
- Support for decompressing data in DEFLATE format
- Support for decompressing data in ZLIB format
- There is a 32bit APB slave interface for configuring decompression parameters and querying register status
- There is a 128-bit AXI master interface for reading compressed data and outputting decompressed data. The AXI master interface supports burst 4/8/16 and single transmissions
- Support one internal 128-bit wide and 64-location deep FIFO(RX_FIFO) for caching source compressed data
- Support one internal 24-bit wide and 64-location deep FIFO(HF_FIFO) for caching intermediate data during decompression
- Built-in a 32KB two-port RAM for storing decompressed data
- Support complete interrupt and error interrupt output
- Support Hash32 check in LZ4 decompression process
- Support the limit_size function of the decompressed data to prevent the memory from being maliciously destroyed during the decompression process
- Support software to stop the decompression process

## 35.2 Block Diagram

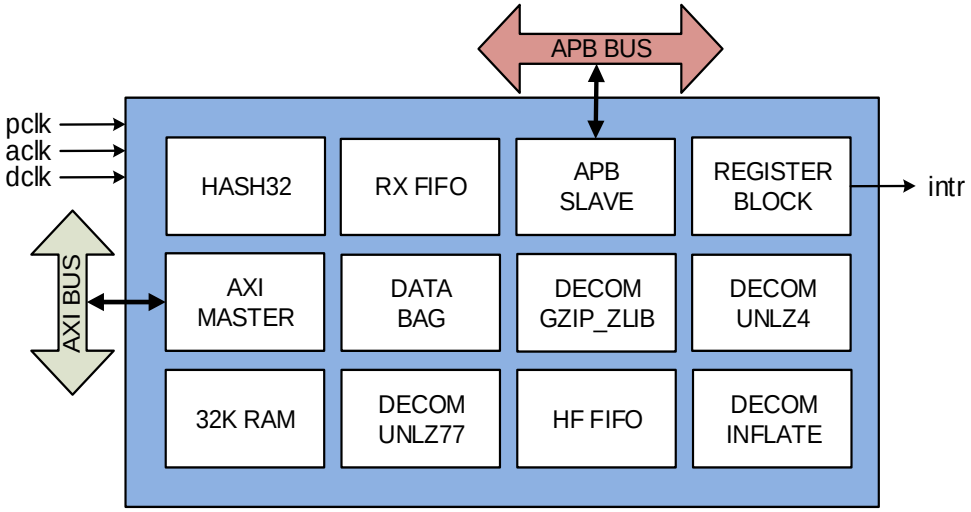

Fig. 35-1 DECOM Block Diagram

## 35.3 Function Description

### 35.3.1 Module Introduction

#### 35.3.1.1 APB INTERFACE

The APB slave interface is used for registers configuration, decompression file parameter reading and interrupt status query, etc.

#### 35.3.1.2 AXI MASTER INTERFACE

The AXI master interface is used to read compressed file data from external storage into the RX_FIFO and output the decompressed data to external storage. When decompressing the

Copyright 2022 © Rockchip Electronics Co., Ltd.

LZ4 file, it is also used to read back data with a matching distance of more than 32 KB from the external storage.

#### 35.3.1.3 RX_FIFO

The RX_FIFO is used to buffer the source compressed file data read back through the AXI master interface. The RX_FIFO is an asynchronous FIFO, the write interface uses aclk, and the read interface uses dclk.

#### 35.3.1.4 Data Bag

The Data Bag reads and bites the data in the RX_FIFO, and extracts the corresponding number of bits according to the needs of the decompression module.

#### 35.3.1.5 UNLZ4 Module

The UNLZ4 module performs file header parsing on the compressed file of LZ4 format, and decompresses the data into LZ77 format (match length-matching distance) data pair or character data, and stores it in HF_FIFO.

#### 35.3.1.6 GZIP_ZLIB

The GZIP_ZLIB module is used to perform file header and file end parsing for compressed files in GZIP format and compressed data in ZLIB format, and the compressed data portion is decompressed by the INFLATE module. The GZIP or ZLIB decompression mode can be configured by configuring the CTRL register.

#### 35.3.1.7 INFLATE Module

INFLATE Module is used to decompress compressed files in DEFLATE format, implement static/dynamic huffman decoding, decompress compressed data in DEFLATE format into LZ77 format (match length-match distance) data pairs or character data, and store them in HF_FIFO.

#### 35.3.1.8 HF_FIFO

The HF_FIFO is used to buffer the LZ77 format (match length-match distance) data pair or character data decompressed by the UNLZ4 module and the INFLATE module, and wait for the UNLZ77 module to further decompress the intermediate data. The HF_FIFO is an asynchronous FIFO, the write interface uses dclk, and the read interface uses aclk.

#### 35.3.1.9 UNLZ77 Module

UNLZ77 is used to implement LZ77 decoding and store the decompressed data in 32K RAM. When the matching distance is less than 32k byte, matching replication is performed in 32K RAM. When the matching distance is greater than 32k byte, the AXI master interface is controlled to perform matching replication in the external storage.

#### 35.3.1.10 32K-RAM

The 32K RAM is used to buffer the decompressed data. During the decompression process, the UNLZ77 module also performs read access to the RAM to complete the data matching.

#### 35.3.1.11 HASH32 Module

In the process of decompressing the LZ4 compressed file, the HASH32 module is used to calculate the hash32 check value of the file header, data block and decompressed data.

#### 35.3.1.12 Interface and Clock

The 32-bit APB Slave interface in DECOM is used for register configuration and interrupt status query interface, using pclk as the interface clock.

DECOM uses 128bit AXI master interface to realize the functions of reading the data to be compressed, decompressing the data output and decompressing LZ4 external matching data; it should be noted that the AXI master interface supports Single and Burst transmission, which only supports incr4, incr8 and Incr16 three transmission types, does not support Wrap transmission. DECOM automatically configures the burst type according to the length of the transmitted data and the starting address. The software configuration is not supported to select the burst type.

DECOM has three sets of clock and reset inputs, pclk and presetn, dclk and drstn, aclk and aresetn. Among them pclk and aclk are APB and AXI bus clocks respectively, and dclk is decompression clock.

### 35.3.2 Data Flow

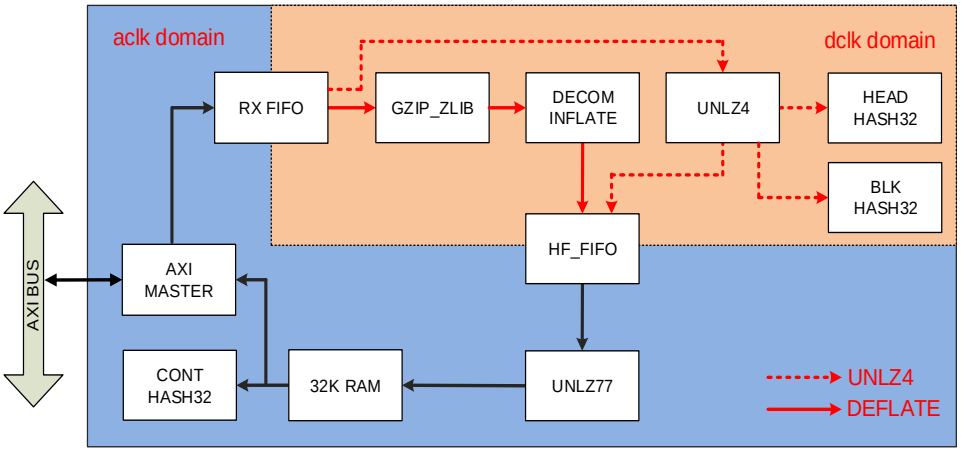

Fig. 35-2 DECOM Data Flow

## 35.4 Register Description

### 35.4.1 Internal Address Mapping

Slave address can be divided into different length for different usage, which is shown as follows.

### 35.4.2 Registers Summary

| Name | Offset | Size | Reset Value | Description |
|---|---|---|---|---|
| DECOM_CTRL | 0x0000 | W | 0x00000000 | Control Register |
| DECOM_ENR | 0x0004 | W | 0x00000000 | Enable Register |
| DECOM_RADDR | 0x0008 | W | 0x00000000 | Read Address |
| DECOM_WADDR | 0x000C | W | 0x00000000 | Write Address |
| DECOM_UDDSL | 0x0010 | W | 0xFFFFFFFF | Undecompressed Data Size |
| DECOM_UDDSH | 0x0014 | W | 0xFFFFFFFF | Undecompressed Data Size |
| DECOM_TXTHR | 0x0018 | W | 0x00000100 | Transmit Threshold Level |
| DECOM_SLEN | 0x0020 | W | 0x00000000 | INFLATE Store Length |
| DECOM_STAT | 0x0024 | W | 0x00000000 | DECOM Status Register |
| DECOM_ISR | 0x0028 | W | 0x00000000 | Interrupt Status Register |
| DECOM_IEN | 0x002C | W | 0x00000000 | Interrupt Enable Register |
| DECOM_AXI_STAT | 0x0030 | W | 0x00000010 | AXI Master Interface State |
| DECOM_TSIZEL | 0x0034 | W | 0x00000000 | Decompressed Data Total Size Lower 32bit |
| DECOM_TSIZEH | 0x0038 | W | 0x00000000 | Decompressed Data Total Size Upper 32bit |
| DECOM_MGNUM | 0x003C | W | 0x00000000 | LZ4 File Magic Number |
| DECOM_FRAME | 0x0040 | W | 0x00000000 | LZ4 File Frame Descriptor |
| DECOM_DICTID | 0x0044 | W | 0x00000000 | Dictionary ID |
| DECOM_CSL | 0x0048 | W | 0x00000000 | LZ4 Content Size(CS) Lower 32-bits |
| DECOM_CSH | 0x004C | W | 0x00000000 | LZ4 Content Size(CS) Upper 32-bits |
| DECOM_LMTSL | 0x0050 | W | 0xFFFFFFFF | Limit Size of Decompressed Data |
| DECOM_LMTSH | 0x0054 | W | 0xFFFFFFFF | Limit Size of Decompressed Data |
| DECOM_GZFHD | 0x0058 | W | 0x00000000 | GZIP/ZLIB File Header Information |
| DECOM_VERSION | 0x00F0 | W | 0x00000926 | DECOM Version Number |

Copyright 2022 © Rockchip Electronics Co., Ltd.

## 35.4.3 Detail Registers Description

### DECOM_CTRL

Address: Operational Base + offset (0x0000)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:6 | RO | 0x0000000 | reserved |
| 5 | RW | 0x0 | ZLIBM<br>ZLIB mode.<br>1'b0: Disable<br>1'b1: Enable<br>When decompressing ZLIB compressed data, ZLIBM must be enabled and DEM should be set to 1. |
| 4 | RW | 0x0 | GZIPM<br>GZIP mode.<br>1'b0: Disable<br>1'b1: Enable<br>When decompressing GZIP files, GZIPM must be enabled and DEM should be set to 1. |
| 3 | RW | 0x0 | CCEN<br>LZ4 content checksum check enable.<br>1'b0: Disable<br>1'b1: Enable<br>In LZ4 files, a 32-bits content checksum will be appended at the end of the file. When CCEN is enabled, DECOM will verify the content checksum to check if the decompressed data is correct. Only valid when decompressing LZ4 files. |
| 2 | RW | 0x0 | BCEN<br>LZ4 block checksum check enable.<br>1'b0: Disable<br>1'b1: Enable<br>In LZ4 files, each data block will be followed by a 4-bytes checksum, calculated by using the xxHash-32 algorithm on the compressed data block. The intention is to detect data corruption(storage or transmission errors) immediately, before decoding. When BCEN is enabled, DECOM will check the block checksum to determine if the block to be decompressed is correct. Only valid when decompressing LZ4 files. |
| 1 | RW | 0x0 | HCEN<br>LZ4 header checksum check enable.<br>1'b0: Disable<br>1'b1: Enable<br>The LZ4 header contains a 1-byte xxh32 checksum value(HC). When HCEN is enabled, DECOM will check the HC to check if the header is correct. Only valid when decompressing LZ4 files. |
| 0 | RW | 0x0 | DEM<br>DECOM mode select.<br>1'b0: UNLZ4 mode. Decompress the file in LZ4 format.<br>1'b1: INFLATE mode. Decompress the file in INFLATE format. If GZIPM=1'b1 or GZLIBM=1'b1, DEM must be set 1. |

### DECOM_ENR

Address: Operational Base + offset (0x0004)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:1 | RO | 0x00000000 | reserved |

*Copyright 2022 © Rockchip Electronics Co., Ltd.*

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 0 | R/WSC | 0x0 | ENR<br>Enables and disables all decompress operations.<br>1'b0: Disable decompressor<br>1'b1: Enable decompressor to work<br>All FIFO buffers and aclk/dclk domain work registers are cleared when the device is disabled. Self clear when decompression is complete.<br>The ENR should be enabled after the other registers are configured. |

**DECOM_RADDR**

Address: Operational Base + offset (0x0008)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:0 | RW | 0x00000000 | RADDR<br>Read address.<br>This register is used to configure the starting address of the file to be decompressed. |

**DECOM_WADDR**

Address: Operational Base + offset (0x000C)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:0 | RW | 0x00000000 | WADDR<br>Write address.<br>This register is used to configure the starting address of the location where the decompressed data is written.<br>Note: WADDR[31:0] must be configured with a 128bit aligned address (WADDR[3:0]==4'b0). |

**DECOM_UDDSL**

Address: Operational Base + offset (0x0010)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:0 | RW | 0xffffffff | UDDSL<br>Undecompressed data size lower 32bits. (Unit:byte)<br>UDDS[63:0] is the total size of undecompressed file. DECOM will read the compressed file data according to the value of UDDS[63:0], but the configuration of this register is optional. If this register is not configured, DECOM will use the default value of 64'hffff_ffff_ffff_ffff, and DECOM will keep reading data until the current decompression process ends. |

**DECOM_UDDSH**

Address: Operational Base + offset (0x0014)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:0 | RW | 0xffffffff | UDDSH<br>Undecompressed data size higher 32bits. |

**DECOM_TXTHR**

Address: Operational Base + offset (0x0018)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:0 | RW | 0x00000100 | TXTHR<br>When the number of 32K_MEM entries is greater than or equal to this value, the DECOM will automatically transfer the data in the 32K_MEM to the external via the AXI Master interface. The value ranges is 0~32256.(Unit:byte) |

*Copyright 2022 © Rockchip Electronics Co., Ltd.*

**DECOM_SLEN**

Address: Operational Base + offset (0x0020)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:0 | RO | 0x00000000 | SLEN<br>INFLATE store block size. (Unit:byte)<br>Indicate the block size when decompressing the store block of INFALTE file. For debugging SLC_ERR. |

**DECOM_STAT**

Address: Operational Base + offset (0x0024)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:2 | RO | 0x00000000 | reserved |
| 1 | RO | 0x0 | LAST<br>Used to indicate whether the currently processed compressed data block is the last one.<br>1'b0: Not last block<br>1'b1: Last block |
| 0 | RO | 0x0 | COMPLETE<br>DECOM complete flag.<br>1'b0: Not complete<br>1'b1: Decompress is complete with no error<br>Only decompress total complete with no error, this flag is set to 1. |

**DECOM_ISR**

Address: Operational Base + offset (0x0028)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|

|---|---|---|---|
| 31:0 | RO | 0x00000000 | TSIZEL<br>The total size of the data after decompression.<br>TSIZE[63:0]. (Unit:byte) |

**DECOM_TSIZEH**

Address: Operational Base + offset (0x0038)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:0 | RO | 0x00000000 | TSIZEH<br>The total size of the data after decompression. |

**DECOM_MGNUM**

Address: Operational Base + offset (0x003C)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:0 | RO | 0x00000000 | MGNUM<br>Magic number of LZ4 is 0x184D2204.<br>If the MGNUM is not 0x184D2204, a magic number error(mn_err) will be generated. And DECOM will stop decompressing. |

**DECOM_FRAME**

Address: Operational Base + offset (0x0040)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:24 | RO | 0x00 | reserved |
| 23:16 | RO | 0x00 | HCC<br>Header checksum byte.<br>One-byte checksum of combined descriptor fields, including optional ones. The value is the second byte of xxh32() using zero as a see, and the full frame descriptor as an input (including optional fields when they are present). A wrong checksum indicates an error in the descriptor. Header checksum is informational and can be skipped.<br>The header checksum check function can be enabled by controlling the HCEN enable signal in the CTRL register. After being turned on, DECOM calculates the hash32 check value based on the data of the frame descriptor part of the LZ4 compressed file, and performs the header checksum byte in the file. In contrast, if they are not equal, an HCC error will be generated and an interrupt will be generated. |
| 15:8 | RO | 0x00 | BD<br>BD byte.<br>Including Block Maximum Size information. This information is useful to help the decoder allocate memory. Size here refers to the original(uncompressed) data size. |
| 7:6 | RO | 0x0 | VN_NUM<br>Version number.<br>2-bits field, must be set to 2'b01. Any other value cannot be decoded by this version of the specification. If the version number is error, Version number error(VNE) will be generated. |
| 5 | RO | 0x0 | BCC_FLG<br>Block checksum flag.<br>If this flag is set, each data block will be followed by a 4-bytes checksum, calculated by using the xxHash-32 algorithm on the raw (compressed) data block. The intention is to detect data corruption (storage or transmission errors) immediately, before decoding. Block checksum usage is optional. |

*Copyright 2022 © Rockchip Electronics Co., Ltd.*

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 4 | RO | 0x0 | BIND_FLG<br>Block independence flag.<br>If this flag is set to "1", blocks are independent. If this flag is set to "0", each block depends on previous ones (up to LZ4 window size, which is 64 KB). In such case, it's necessary to decode all blocks in sequence. Block dependency improves compression ratio, especially for small blocks. On the other hand, it makes random access or multi-threaded decoding impossible. For debugging. |
| 3 | RO | 0x0 | CS_FLG<br>Content size flag.<br>If this flag is set, the uncompressed size of data included within the frame will be present as an 8 bytes unsigned little endian value, after the flags. Content size usage is optional. |
| 2 | RO | 0x0 | CCC_FLG<br>Content checksum flag.<br>If this flag is set, a 32-bits content checksum will be appended after the EndMark. |
| 1 | RO | 0x0 | reserved |
| 0 | RO | 0x0 | DICT_FLG<br>Dictionary ID flag.<br>If this flag is set, a 4-bytes Dict-ID field will be present, after the descriptor flags and the Content Size. If this flag is set, Dictionary ID error will be generated. DECOM will stop decompressing. |

**DECOM_DICTID**

Address: Operational Base + offset (0x0044)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:0 | RO | 0x00000000 | DICTID<br>Dictionary ID in the compressed file header.<br>Dictionary ID is only present if the DID_FLG is set. It works as a kind of "known prefix" which is used by both the compressor and the decompressor to "warm-up" reference tables. |

**DECOM_CSL**

Address: Operational Base + offset (0x0048)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:0 | RO | 0x00000000 | CSL<br>Content size(CS) lower 32-bits. (Unit:byte)<br>CS[63:0] is the original(uncompressed) size. This information is optional in LZ4 file header, and only present if CS_FLG is set.<br>CS[63:0]={CSH, CSL}; |

**DECOM_CSH**

Address: Operational Base + offset (0x004C)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:1 | RO | 0x00000000 | reserved |
| 0 | RO | 0x0 | CSH<br>Content size(CS) upper 32-bits. |

**DECOM_LMTSL**

Address: Operational Base + offset (0x0050)

*Copyright 2022 © Rockchip Electronics Co., Ltd.* 

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:0 | RW | 0xffffffff | LMTSL<br>Limit size of decompressed data lower 32bits. (Unit:byte)<br>When the amount of decompressed data is greater than the LMTS, DSOLI interrupt is generated and the decompression process is stopped. |

**DECOM_LMTSH**

Address: Operational Base + offset (0x0054)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:0 | RW | 0xffffffff | LMTSH<br>Limit size of decompressed data higher 32bits. |

**DECOM_GZFHD**

## 35.5 Application Notes

- After configuring the decompression mode and other decompression parameters, configure the decompression enable register ENR
- When the decompression is not completed, setting ENR from 1 to 0 will force the decompression process to stop and DECOM will return to the IDLE state. Need to reconfigure and enable DECOM to start the next decompression
- When an error is encountered in the decompression, DECOM will immediately stop the decompression process, set the relevant status register, and generate the corresponding interrupt
- After the decompression process is stopped, ENR will automatically change to 0
- After the decompression process is stopped, DSI will be set to 1. If DSIEN is 1, an interrupt will be generated; if DSIEN is 0, no interrupt will be generated
- After the decompression process is stopped, COMPLETE (STAT[0]) is not set to 1 if there is an error in the decompression process; COMPLETE is set to 1 only when the decompression is complete and there are no errors

# Chapter 36 RKNN

## 36.1 Overview

RKNN is the process unit which is dedicated to neural network. It is designed to accelerate the neural network arithmetic in field of AI (artificial intelligence) such as machine vision and natural language processing. The variety of applications for AI is expanding, and currently provides functionality in a variety of areas, including face tracking as well as gesture and body tracking, image classification, video surveillance, automatic speech recognition (ASR) and advanced driver assistance systems (ADAS).
RKNN supports the following features:

- Include triple NPU CORE
- Support triple core co-work, dual core co-work, and work independently
- AHB interface used for configuration only support single
- AXI interface used to fetch data from memory
- Support integer 4, integer 8, integer 16, float 16, Bfloat 16 and tf32 operation
- 1024x3 integer 8 MAC operations per cycle
- 512x3 integer 16 MAC operations per cycle
- 512x3 float 16 MAC operations per cycle
- 512x3 bfloat 16 MAC operations per cycle
- 256x3 tf32 MAC operation per cycle
- 2048x3 integer 4 MAC operation per cycle
- 384KBx3 internal buffer
- Inference Engine: TensorFlow, Caffe, Tflite, Pytorch, Onnx NN, Android NN, etc.

# 36.3 Function Description

### 36.3.1 1.3.1 AHB/AXI Interface

The AXI master interface is used to fetch data from memory that is attached to the Soc AXI interconnect. The AHB slave interface is used to access the registers for configuration, debug and test.

### 36.3.2 1. 3. 2 Neural Network Accelerating Engine

As the unit name, this engine is the main process unit for Neural Network arithmetic. This unit include convolution pre-process controller, internal buffer, mac array, accumulator. It provides parallel convolution MAC for recognition functions and int4, int8, int16, fp16, bfloat16 and tf16 are supported.

### 36.3.3 1. 3. 3 Data Processing Unit

Data Processing Unit mainly process the single data calculate, such as leaky_relu, relu, relux, sigmoid, tanh…etc. It also provides function: softmax, transpose, data format conversion, …etc.

### 36.3.4 1. 3. 4 Planar Processing Unit

Planar Processing Unit mainly provide planar function followed by output data from Data Processing Unit, such as average pooling, max pooling, min pooling… are supported.

Copyright 2022 © Rockchip Electronics Co., Ltd.

### 36.3.5 1. 3. 5 Register File Fetch Unit

Register File Fetch Unit fetch register configuration from external system memory through AXI
interface.

## 36.4 Register Description

### 36.4.1 Internal Address Mapping

Slave address can be divided into different length for different usage, which is shown as follows.

Table 1- 1 RKNN Address Mapping

| Base Address[15:12] | Device | Address Length | Offset Address Range |
|---|---|---|---|
| 4'h0 | PC | 4K BYTE | 0x0000 ~ 0x0fff |
| 4'h1 | CNA | 4K BYTE | 0x1000 ~ 0x1fff |
| 4'h3 | CORE | 4K BYTE | 0x3000 ~ 0x3fff |
| 4'h4 | DPU | 4K BYTE | 0x4000 ~ 0x4fff |
| 4'h5 | DPU_RDMA | 4K BYTE | 0x5000 ~ 0x5fff |
| 4'h6 | PPU | 4K BYTE | 0x6000 ~ 0x6fff |
| 4'h7 | PPU_RDMA | 4K BYTE | 0x7000 ~ 0x7fff |
| 4'h8 | DDMA | 4K BYTE | 0x8000 ~ 0x8fff |
| 4'h9 | SDMA | 4K BYTE | 0x9000 ~ 0x9fff |
| 4'hf | GLOBAL | 4 BYTE | 0xf000 ~ 0xf004 |

### 36.4.2 Registers Summary

| Name | Offset | Size | Reset Value | Description |
|---|---|---|---|---|
| RKNN_pc_operation_enable | 0x0008 | W | 0x00000000 | Operation Enable |
| RKNN_pc_base_address | 0x0010 | W | 0x00000000 | PC address register |
| RKNN_pc_register_amounts | 0x0014 | W | 0x00000000 | Register amount for each task |
| RKNN_pc_interrupt_mask | 0x0020 | W | 0x0001FFFF | Interrupt Mask |
| RKNN_pc_interrupt_clear | 0x0024 | W | 0x00000000 | Interrupt clear |
| RKNN_pc_interrupt_status | 0x0028 | W | 0x00000000 | Interrupt status |
| RKNN_pc_interrupt_raw_status | 0x002C | W | 0x00000000 | Interrupt raw status |
| RKNN_pc_task_con | 0x0030 | W | 0x00000000 | Task control register |
| RKNN_pc_task_dma_base_addr | 0x0034 | W | 0x00000000 | Task Base address |
| RKNN_pc_task_status | 0x003C | W | 0x00000000 | Task status register |
| RKNN_cna_s_status | 0x1000 | W | 0x00000000 | Single register group status |
| RKNN_cna_s_pointer | 0x1004 | W | 0x00000000 | Single register group pointer |
| RKNN_cna_operation_enable | 0x1008 | W | 0x00000000 | Operation Enable |
| RKNN_cna_conv_con1 | 0x100C | W | 0x00000000 | Convolution control register1 |

## 36.4.3 Detail Registers Description

**RKNN_pc_operation_enable**

Address: Operational Base + offset (0x0008)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:1 | RO | 0x00000000 | reserved |
| 0 | RW | 0x0 | op_en<br>PC operation enable.<br>1'd0: Disable PC module;<br>1'd1: Enable PC module to fetch register for each task. |

**RKNN_pc_base_address**

Address: Operational Base + offset (0x0010)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:4 | RW | 0x0000000 | pc_source_addr<br>PC base address.<br>This is the address of DMA instruction where it located. |
| 3:1 | RO | 0x0 | reserved |
| 0 | RW | 0x0 | pc_sel<br>PC mode enable.<br>1'd0: PC mode, use AXI DMA to fetch register config;<br>1'd1: Slave mode, use AHB to set register. |

**RKNN_pc_register_amounts**

Address: Operational Base + offset (0x0014)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:16 | RO | 0x0000 | reserved |
| 15:0 | RW | 0x0000 | pc_data_amount<br>Data amount.<br>The register number need to be fetched of one task. Each register takes 64 bits, it is combined as following:<br>bit[63:48] indicates which block the register forward to.<br>bit[47:16] the register's value<br>bit[15: 0] the register's offset address in each block.<br>bit[56]= 1 means this register is for pc block.<br>bit[57]= 1 CNA<br>bit[59]= 1 CORE<br>bit[60]= 1 DPU<br>bit[61]= 1 DPU_RDMA<br>bit[62]= 1 PPU<br>bit[63]= 1 PPU_RDMA<br>bit[55]= 1 to set each block's op_en<br>eg. 64'h0081_0000_007f_0008 will set each block's op_en(CNA, CORE, ..., PPU_RDMA).<br>note: op_en is strongly recommended set at the end of register list.<br>before op_en, 64'h0041_xxxx_xxxx_xxxx must be set. |

**RKNN_pc_interrupt_mask**

Address: Operational Base + offset (0x0020)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:17 | RO | 0x0000 | reserved |
| 16:0 | RW | 0x1ffff | int_mask<br>Interrupt mask.<br>mask[0 ]: CNA feature group 0 interrupt mask. set 1 to enable interrupt;<br>mask[1 ]: CNA feature group 1;<br>mask[2 ]: CNA weight group 0;<br>mask[3 ]: CNA weight group 1;<br>mask[4 ]: CNA csc group 0;<br>mask[5 ]: CNA csc group 1;<br>mask[6 ]: CORE group 0;<br>mask[7 ]: CORE group 1;<br>mask[8 ]: DPU group 0;<br>mask[9 ]: DPU group 1;<br>mask[10]: PPU group 0;<br>mask[11]: PPU group 1;<br>mask[12]: DMA read error;<br>mask[13]: DMA write error;<br>Note: In pc mode, int mask set the last one task's interrupt masking. |

**RKNN_pc_interrupt_clear**

Address: Operational Base + offset (0x0024)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:17 | RO | 0x0000 | reserved |
| 16:0 | W1C | 0x00000 | int_clr<br>Interrupt clear.<br>done_clr[0 ]: CNA feature group 0 interrupt clear;<br>done_clr[1 ]: CNA feature group 1;<br>done_clr[2 ]: CNA weight group 0;<br>done_clr[3 ]: CNA weight group 1;<br>done_clr[4 ]: CNA csc group 0;<br>done_clr[5 ]: CNA csc group 1;<br>done_clr[6 ]: CORE group 0;<br>done_clr[7 ]: CORE group 1;<br>done_clr[8 ]: DPU group 0;<br>done_clr[9 ]: DPU group 1;<br>done_clr[10]: PPU group 0;<br>done_clr[11]: PPU group 1;<br>done_clr[12]: DMA read error;<br>done_clr[13]: DMA write error. |

**RKNN_pc_interrupt_status**

Address: Operational Base + offset (0x0028)

*Copyright 2022 © Rockchip Electronics Co., Ltd.* 

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:17 | RO | 0x0000 | reserved |
| 16:0 | W1C | 0x00000 | int_st<br>Interrupt status.<br>int_st[0 ]: CNA feature group 0 interrupt status, which and with mask bit;<br>int_st[1 ]: CNA feature group 1;<br>int_st[2 ]: CNA weight group 0;<br>int_st[3 ]: CNA weight group 1;<br>int_st[4 ]: CNA csc group 0;<br>int_st[5 ]: CNA csc group 1;<br>int_st[6 ]: CORE group 0;<br>int_st[7 ]: CORE group 1;<br>int_st[8 ]: DPU group 0;<br>int_st[9 ]: DPU group 1;<br>int_st[10]: PPU group 0;<br>int_st[11]: PPU group 1;<br>int_st[12]: DMA read error;<br>int_st[13]: DMA write error. |

**RKNN_pc_interrupt_raw_status**

Address: Operational Base + offset (0x002C)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:17 | RO | 0x0000 | reserved |
| 16:0 | W1C | 0x00000 | int_raw_st<br>Interrupt raw status.<br>int_st[0 ]: CNA feature group 0 interrupt raw status;<br>int_st[1 ]: CNA feature group 1;<br>int_st[2 ]: CNA weight group 0;<br>int_st[3 ]: CNA weight group 1;<br>int_st[4 ]: CNA csc group 0;<br>int_st[5 ]: CNA csc group 1;<br>int_st[6 ]: CORE group 0;<br>int_st[7 ]: CORE group 1;<br>int_st[8 ]: DPU group 0;<br>int_st[9 ]: DPU group 1;<br>int_st[10]: PPU group 0;<br>int_st[11]: PPU group 1;<br>int_st[12]: DMA read error;<br>int_st[13]: DMA write error. |

**RKNN_pc_task_con**

Address: Operational Base + offset (0x0030)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:14 | RO | 0x00000 | reserved |

*Copyright 2022 © Rockchip Electronics Co., Ltd.*

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 13 | W1C | 0x0 | task_count_clear<br>Task counter clear register.<br>Clear the counter that counting current task. Before task started, it is suggested to clear. |
| 12 | RW | 0x0 | task_pp_en<br>PC task ping-pong mode enable.<br>1'd0: Ping-pong mode off. The second group register setting is fetched after first group task operation is finished;<br>1'd1: Tasks' registers are fetched in ping-pong mode. The second group register setting is fetched immediately after first group's register fetching is finished. |
| 11:0 | RW | 0x000 | task_number<br>PC task number.<br>Set the total task number to be executed. |

**RKNN_pc_task_dma_base_addr**

Address: Operational Base + offset (0x0034)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:4 | RW | 0x0000000 | dma_base_addr<br>Task base address.<br>This is for each DMA's base address.<br>For feature DMA, weight DMA, DPU DMA, PPU DMA, the address is set as offset address. Final address appear on AXI bus is base address + offset address. |
| 3:0 | RO | 0x0 | reserved |

**RKNN_pc_task_status**

Address: Operational Base + offset (0x003C)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:28 | RO | 0x0 | reserved |
| 27:0 | RW | 0x0000000 | task_status<br>Task status.<br>[11:0]: Current task counter value;<br>[12]: Indicate the first task is operating;<br>[13]: Indicate the last task is operating;<br>[12]: Indicate the first task's register is fetching;<br>[13]: Indicate the last task's register is fetching. |

**RKNN_cna_s_status**

Address: Operational Base + offset (0x1000)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:18 | RO | 0x0000 | reserved |

Copyright 2022 © Rockchip Electronics Co., Ltd.

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 17:16 | RO | 0x0 | status_1<br>Executer 1 status.<br>2'd0: Executer 1 is in idle state;<br>2'd1: Executer 1 is operating;<br>2'd2: Executer 1 is operating, executer 1 is waiting to operate;<br>2'd3: Reserved. |
| 15:2 | RO | 0x0000 | reserved |
| 1:0 | RO | 0x0 | status_0<br>Executer 0 status.<br>2'd0: Executer 0 is in idle state;<br>2'd1: Executer 0 is operating;<br>2'd2: Executer 0 is operating, executer 1 is waiting to operate;<br>2'd3: Reserved. |

**RKNN_cna_s_pointer**

Address: Operational Base + offset (0x1004)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:17 | RO | 0x0000 | reserved |
| 16 | RO | 0x0 | executer<br>Which register group to be used.<br>1'd0: Executer group 0;<br>1'd1: Executer group 1. |
| 15:6 | RO | 0x000 | reserved |
| 5 | W1C | 0x0 | executer_pp_clear<br>Clear executer group pointer.<br>Set this bit to 1 to clear pointer to 0. |
| 4 | W1C | 0x0 | pointer_pp_clear<br>Clear register group pointer.<br>Set this bit to 1 to clear pointer to 0. |
| 3 | RW | 0x0 | pointer_pp_mode<br>Register group ping-pong mode.<br>1'd0: Pointer ping-pong by executer;<br>eg. if current executer is 0, next pointer will toggle to 1;<br>1'd1: Pointer ping-pong by pointer;<br>eg. if current pointer is 0, next pointer will toggle to 1. |
| 2 | RW | 0x0 | executer_pp_en<br>Executer group ping-pong enable.<br>1'd0: Disable;<br>1'd1: Enable. |
| 1 | RW | 0x0 | pointer_pp_en<br>Register group ping-pong enable.<br>1'd0: Disable;<br>1'd1: Enable. |

# 36.5 Application Notes

## 36.5.1 Ping-pong registers

In order to reduce the time of fetch registers, every Calculate Core and Control Core of RKNN has its owner ping-pong registers. Configure the group 0 when use the group 1, and configure the group 1 when use group 0. As a result of hiding the time of fetch registers. Writing S_POINTER of every block can enable this function.

## 36.5.2 Clock and Reset

### 1.5.2.1 Clock Domains

RKNN has two clock domains, one is AHB clock, the other is AXI clock. AHB clock, which is the clock for AHB interface, while AXI clock, which is the clock for AXI interface. AXI clock also used for core clock for every Calculate Core and Control Core. Clock frequency can be controlled by CRU, please refer to the relevant sections. Automatic localized clock gating is employed throughout the design in order to minimize the dynamic power consumption. Almost all of the flip-flops are clock gated in the design. Block level clock gating also implemented in every separate block. If a block and the interface to the block are both idle, then the clock of that block will be gated automatically. This feature can be disabled by software.

### 1.5.2.2 NPU Reset

Correspond to the clock domain, there are two reset signals. Aresetn, the reset signal for AXI interface and every Calculate Core and Control Core. Hresetn is the AHB interface reset pin and which is synchronized to the AHB clock domain.

All the two signals must be asserted for a minimum of 32 core clock cycles, using the slowest of the two clocks. Then two signals must be release at the same time.

## 36.5.3 NPU Interrupt Application

Copyright 2022 © Rockchip Electronics Co., Ltd.

RKNN has 3 interrupt output signal and it remains asserted until the host processor clears the interrupt. Each bit of PC_INTERRUPT_STATUS represents one of the 17 possible events that the RKNN can signal to the host processor. By setting the bits of the interrupt enable register (PC_INTERRUPT_MASK) the programmer can control which of those events will generate an interrupt.

### 36.5.4 NPU operate flow

RKNN has two types of work mode: slave configured mode and pc work mode. Pc work mode need to initial register information to the system memory, then obey flowing flows as Figure 1-3 shows.

The information of registers initial to the system memory need to generate by the op you want to specify. And we describe the normal work flows by describe the slave configured mode.

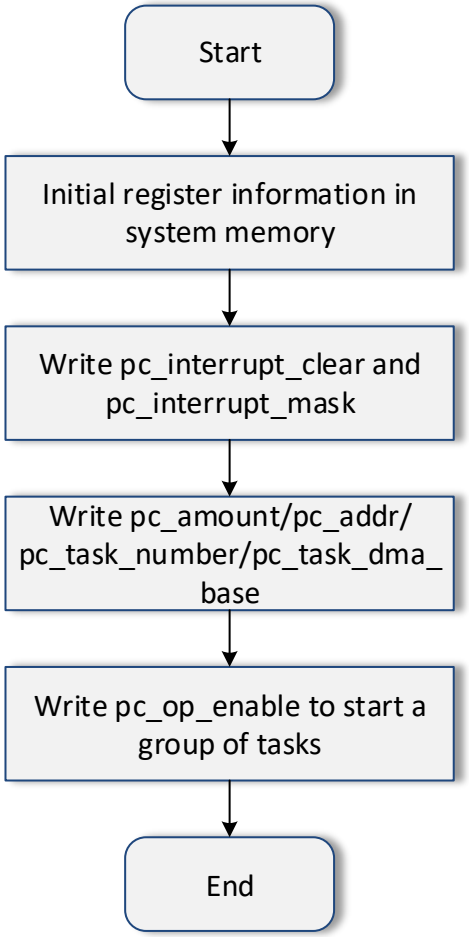

Fig. 36-3 PC flow

Convolution flow

RKNN supports variety of convolution and matrix multiplication. If use the MAC array to calculate, the work flow should obey the Figure 1-4, and if use DPU CORE calculate, work flow should obey the Figure 1-5.

Copyright 2022 © Rockchip Electronics Co., Ltd.

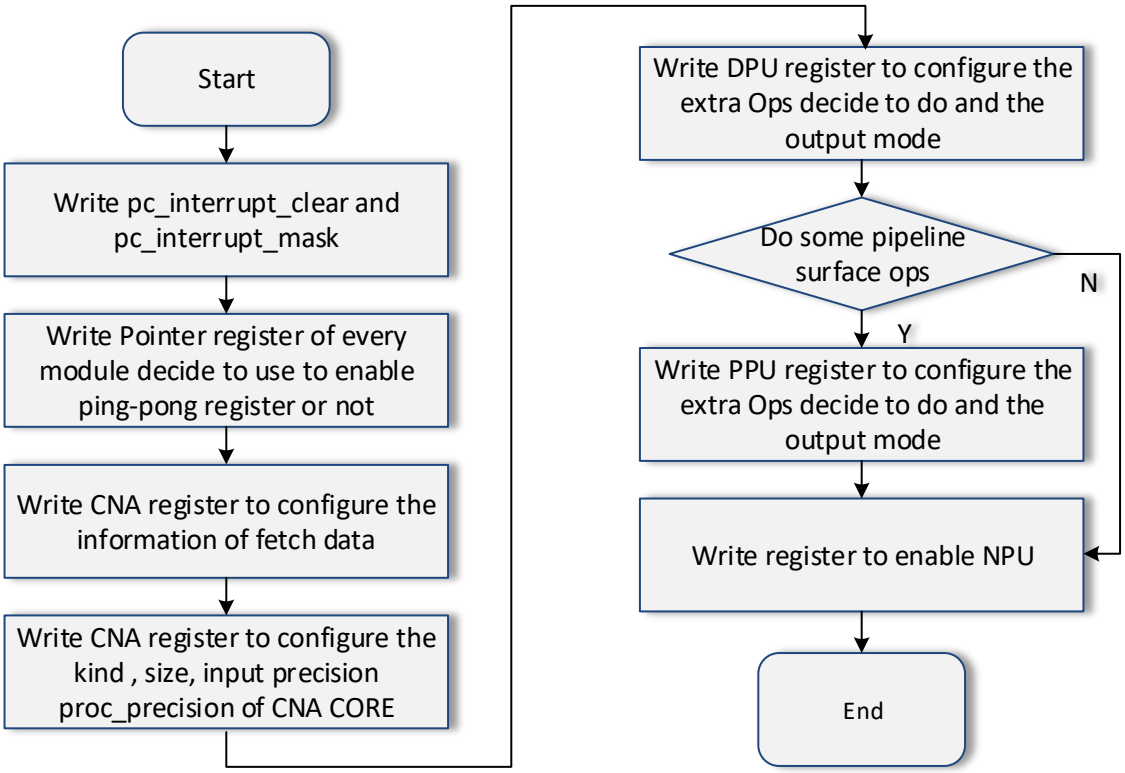

Fig. 36-4 Convolution flow 1

In step 1, do not set PPU mask bit if don't use PPU.

In step 3, you need to configure the size of feature map, and the input precision, process precision, grains, entries and weight size, including weight height, weight width, kernels and weight bytes etc.

In step 4, you need to configure process precision, conv_mode and auto gating registers of CMAC and CNA sequence controller.

In step 5, you can specify some operators to the outputs of convolution according to configure the DPU_CORE. DPU CORE has some fixed operators, also you can specify some programmed operators.

In step 6, you can do some extra operators to the outputs of DPU, pooling for example.

Copyright 2022 © Rockchip Electronics Co., Ltd.

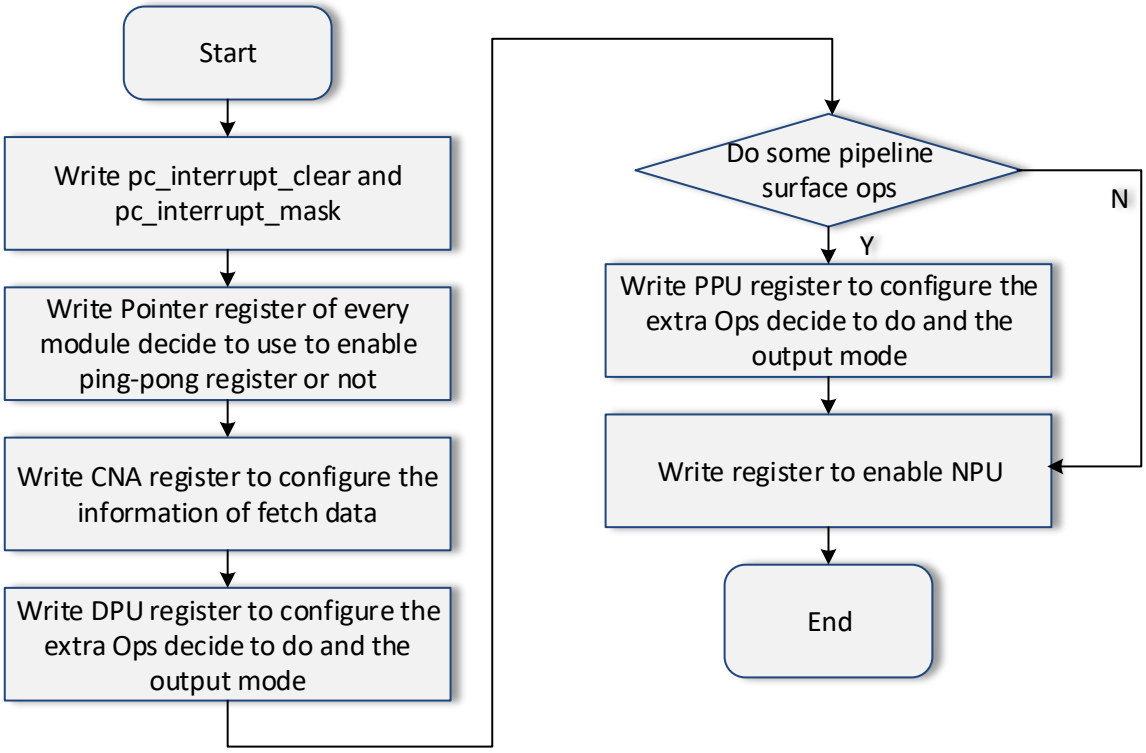

Fig. 36-5 Convolution flow 2

In step 3, you need to configure the size of feature map, and the input precision, process precision, grains, entries and weight size, including height, width, kernels and weight bytes etc. Here we supply zero skipping switch, if there's a lot of zero or some number else in the feature map, you can enable zero skipping by writing cna_fc_con0, cna_fc_con1 and cna_fc_con2, as a result of without reading the weights correspond to the pixel in the feature map. In zero skipping mode, you can specify the feature map size for read different from the feature map size for calculate.

If enable zero skipping, the conv_mode of DPU must configure to be 3, and must bypass the BS_CORE. The alu_src must set to be 0, the mul_src must set to be 1, and the alu_algo must set be 3. We bypass BS_CORE, and use BN_CORE to calculate convolution, so the extra operators have to achieve by EW_CORE. But we use NRDMA to read operands to EW_CORE when ew_src is 1.

Pooling flow

You can use PPU in two ways, pipeline with DPU, and flying mode independently.The first one is described above, we describe the second flow below.

Copyright 2022 © Rockchip Electronics Co., Ltd.

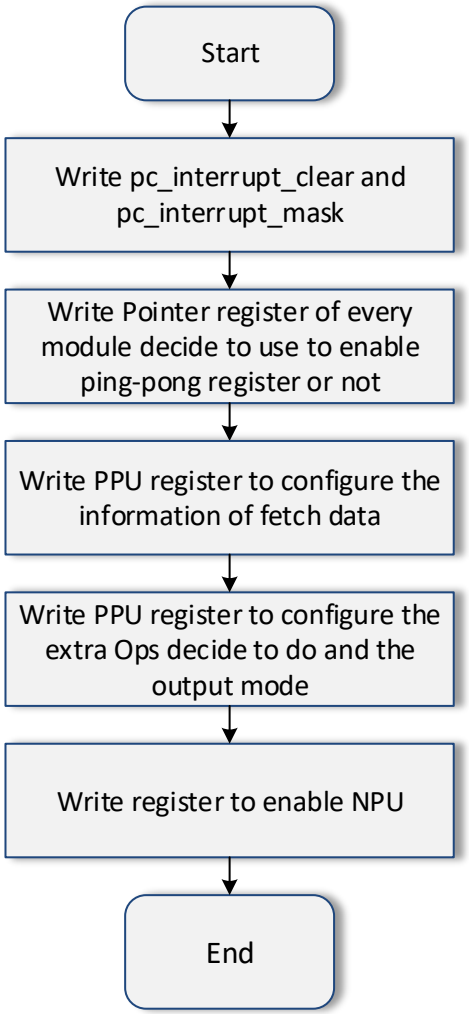

Fig. 36-6 Pooling flow

In step 4, we supply two type of output mode, 8byte align per pixel and non-align mode. In some case with uncomfortable feature map size, you can enable non-align mode by writing ppu_misc_ctrl_nonalign and ppu_misc_ctrl_surf_len.

Separate op flow

As for the operators that RKNN do not fixed, you can combine DPU and PPU to achieve it. Following we describe the DPU flying mode flow.

Copyright 2022 © Rockchip Electronics Co., Ltd.

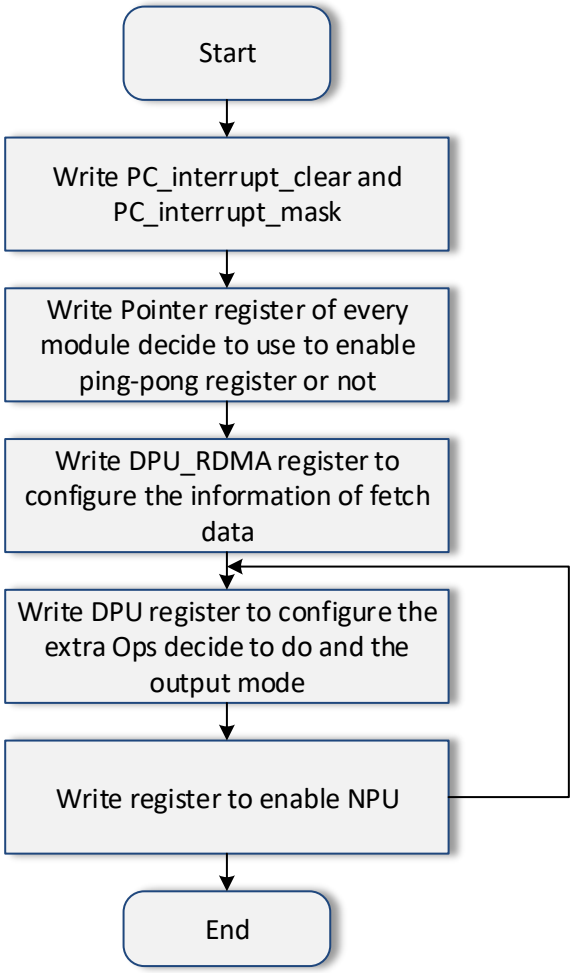

Fig. 36-7 DPU flying mode flow

In step 3, you can enable MRDMA, BRDMA, NRDMA, ERDMA to fetch data. RKNN supports 6 types of data input precision.

In step 4, you can configure BS_ALU_BYPASS, BS_MUL_BYPASS, BS_RELU_BYPASS, BS_MUL_PRELU, BS_MUL_SHIFT, BS_RELUX_EN etc. to specify the operators you want to achieve.

# Chapter 37 Video Capture (VICAP)

## 37.1 Overview

The Video Capture, receives the data from Camera via DVP/MIPI, and transfers the data into system main memory by AXI bus.

- Support BT601 YCbCr 422 8bit input, RAW 8/10/12bit input
- Support BT656 YCbCr 422 8bit progressive/interlace input
- Support BT1120 YCbCr 422 16bit progressive/interlace input, single/dual-edge sampling
- Support 2/4 channels mixed BT656/BT1120 YCbCr 422 8/16bit progressive/interlace input
- Support YUYV sequence configurable
- Support the polarity of hsync and vsync configurable
- Support receiving six interfaces of MIPI CSI/DSI, up to four IDs for each interface
- Support five CSI data formats: RAW8/10/12/14, YUV422
- Support three modes of HDR: virtual channel mode, identification code mode, line counter mode
- Support window cropping
- Support RAW data through to ISP0/1
- Support four channels of 8/16/32 times down-sampling for RAW data
- Support virtual stride when write to DDR
- Support NV16/NV12/YUV400/YUYV output format for YUV data
- Support compact/non-compact output format for RAW data
- Support MMU
- Support soft reset, auto-reset when DMA error

## 37.2 Block Diagram

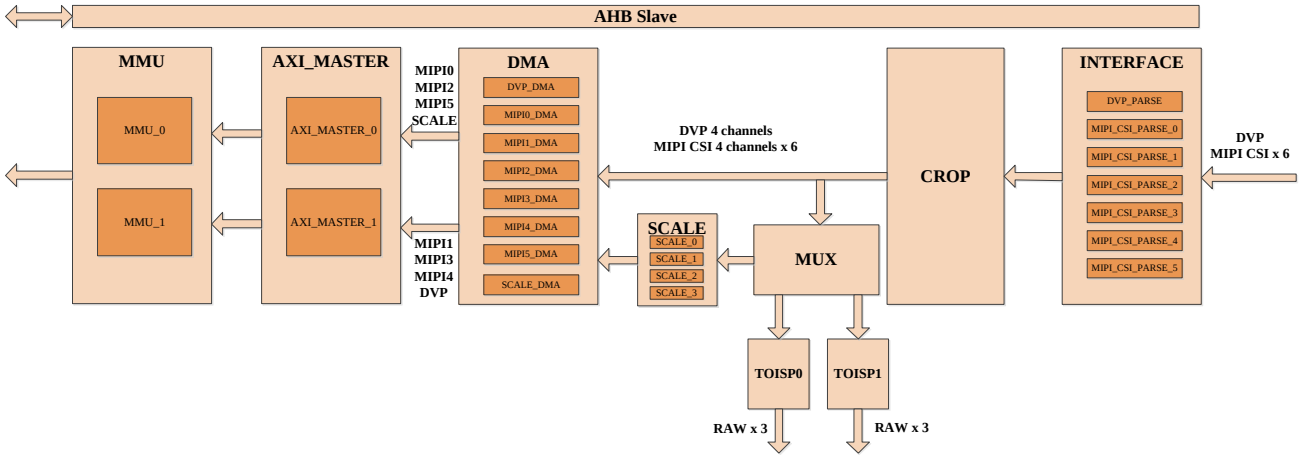

Fig. 37-1 VICAP Block Diagram

VICAP comprises with:

- AHB Slave
- AXI Master
- MMU
- INTERFACE
- CROP
- SCALE
- TOISP0/1
- DMA

## 37.3 Function Description

### 37.3.1 Interface

Translate the input video data(DVP/MIPI CSI) into the requisite data format

- DVP BT656/BT1120 format

Copyright 2022 © Rockchip Electronics Co., Ltd.

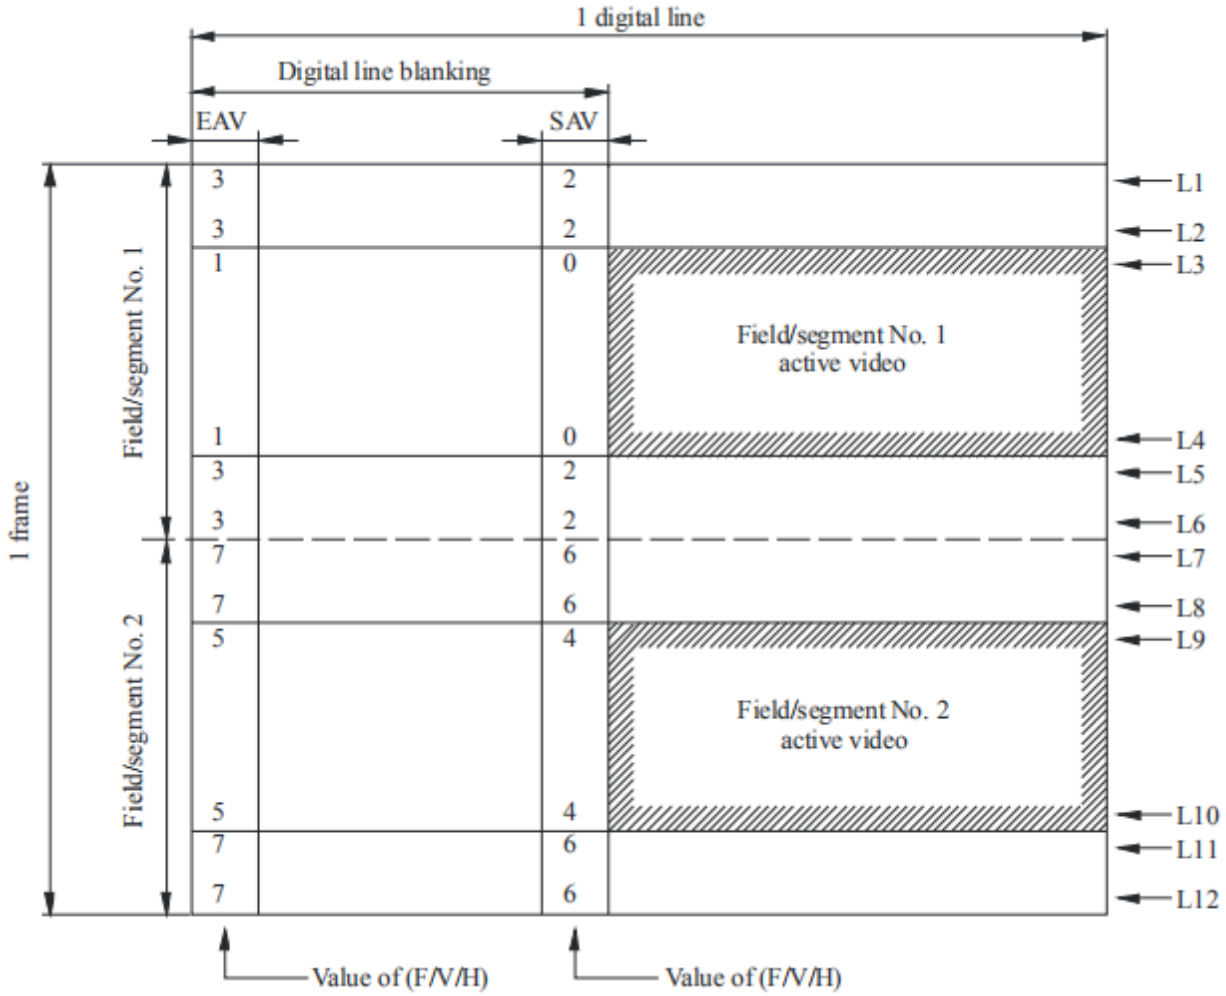

Fig. 37-2 BT656/BT1120 interlace timing relationship

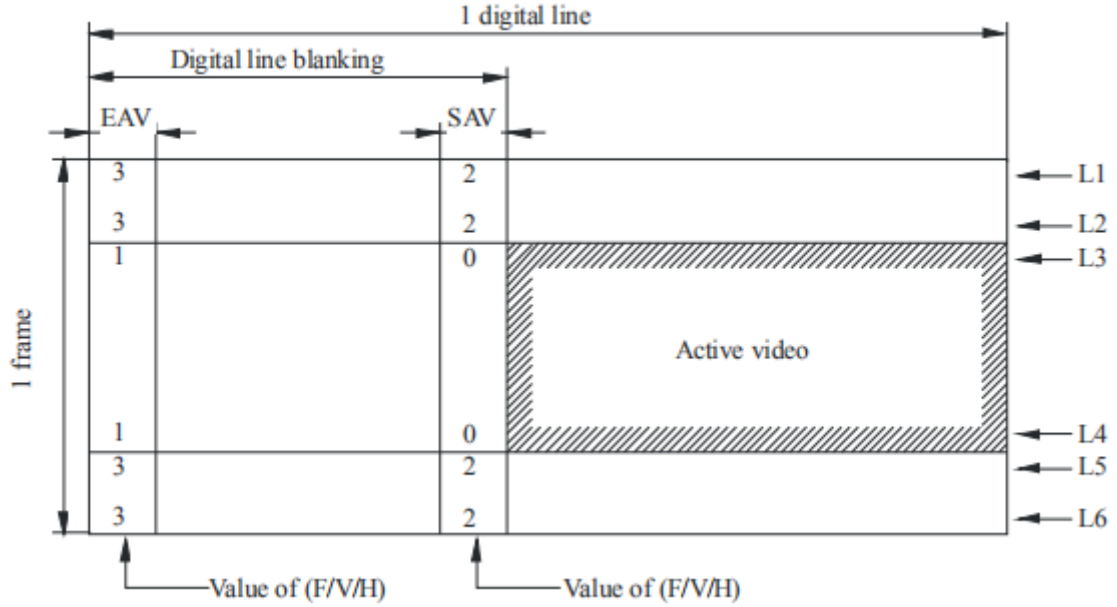

Fig. 37-3 BT656/BT1120 progressive timing relationship

- MIPI CSI YUV422 format

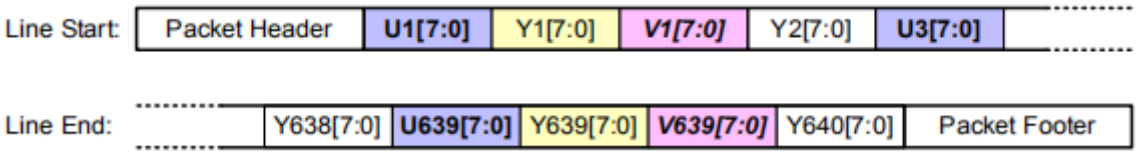

Fig. 37-10 MIPI CSI YUV422 format

## 37.3.2 Crop

Bypass or crop the source video data to a smaller size destination.

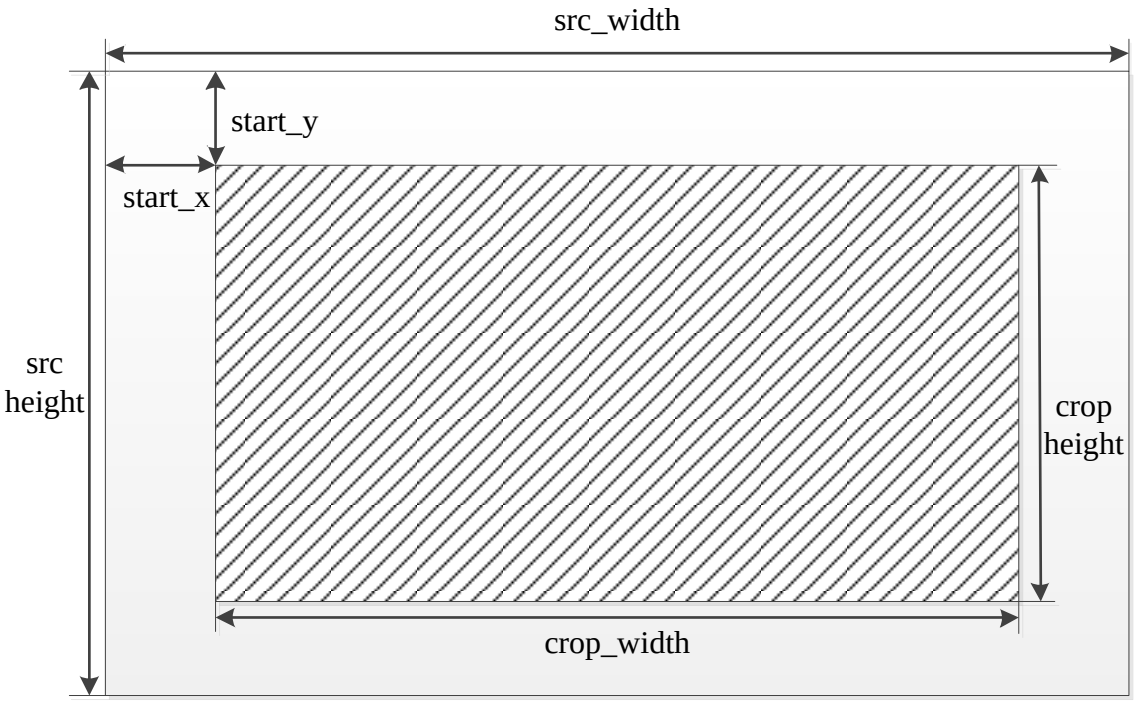

Fig. 37-11 Crop

## 37.3.3 Scale

Scale down for RAW data.

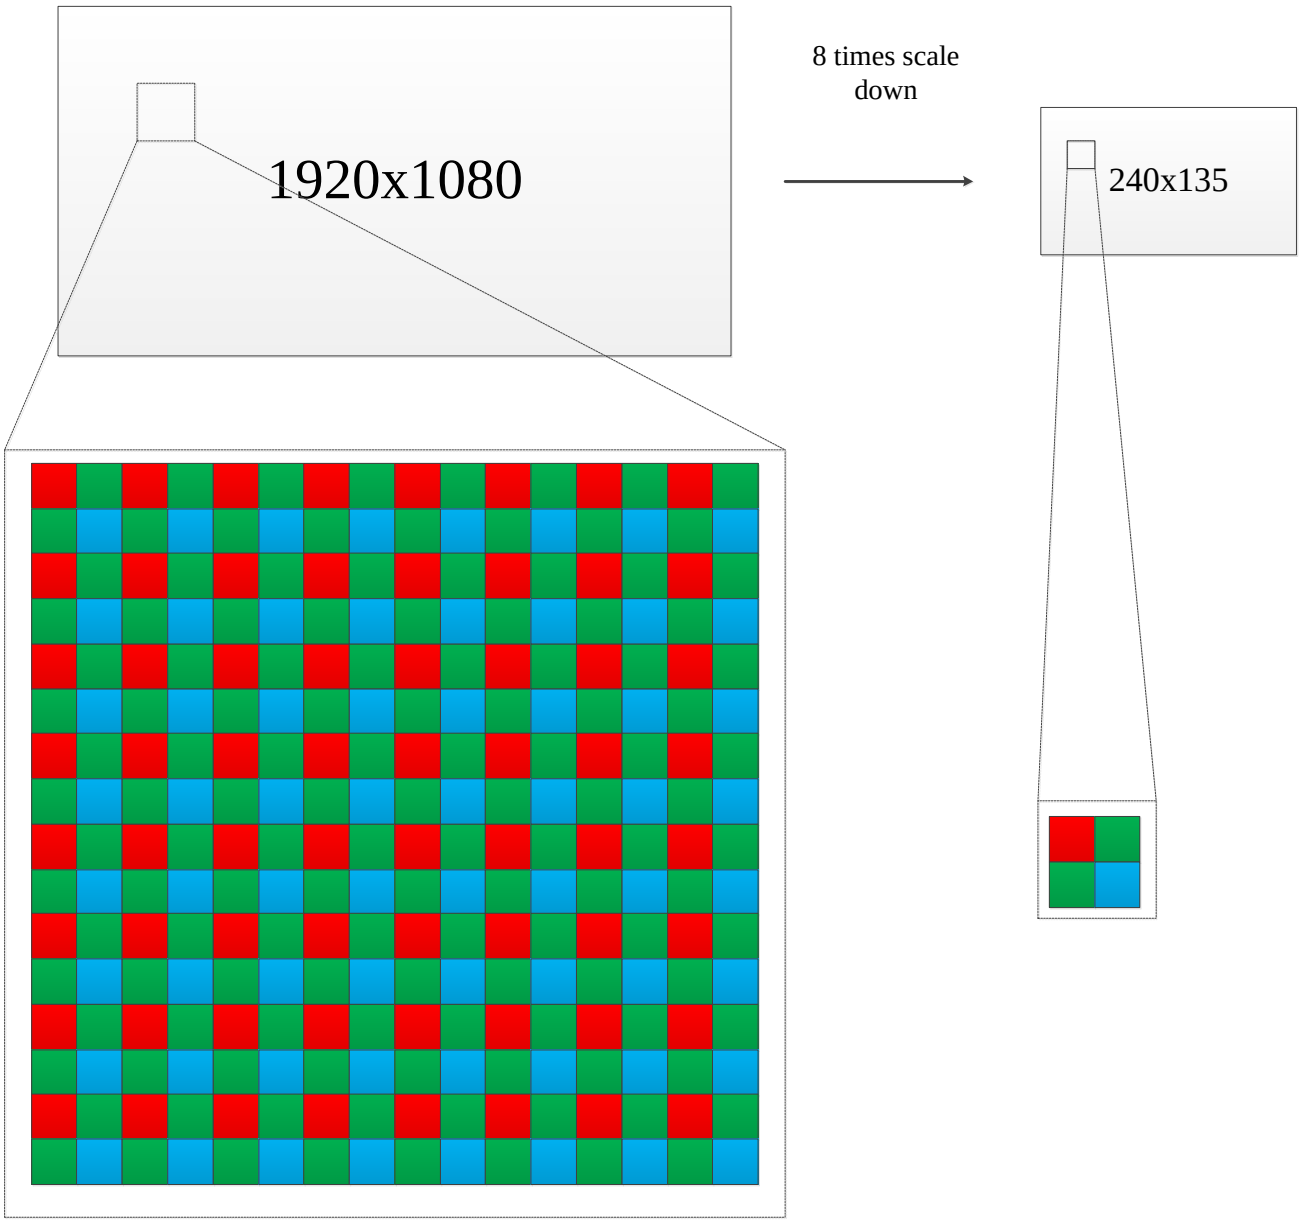

Fig. 37-12 8 times Scale down

### 37.3.4 Toisp

The parsed video data can go straight to ISP0/1 for real-time processing.

### 37.3.5 DMA

The DMA is used to transfer the data from crop module to the AXI master block which will send the data to the AXI bus.

- NV16

- Noncompact RAW

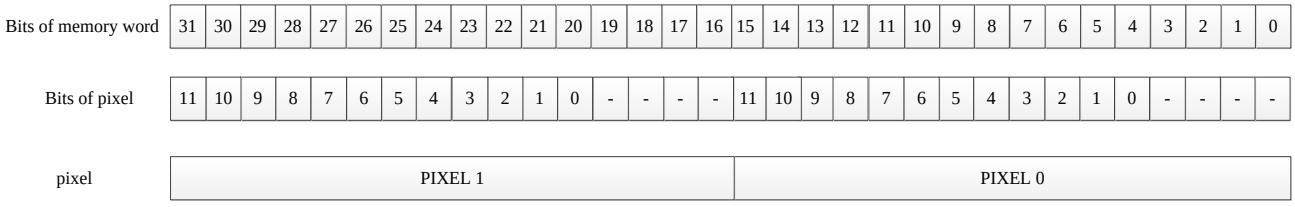

Fig. 37-18 noncompact RAW12(high align)

### 37.3.6 AXI Master

Transmit the data to chip memory via the AXI Master.

### 37.3.7 MMU

Map the virtual address to physical address.

### 37.3.8 AHB Slave

Host configure the registers via the AHB Slave.

# 37.4 VICAP Register Description

## 37.4.1 Internal Address Mapping

Slave address can be divided into different length for different usage, which is shown as follows.

Table 37-1 VICAP Address Mapping

| Base Address[11:8] | Device | Address Length | Offset Address Range |
|---|---|---|---|
| 4'b0000 | Global/DVP | 256 BYTE | 0x0000 ~ 0x00ff |
| 4'b0001 | MIPI0 | 256 BYTE | 0x0100 ~ 0x01ff |
| 4'b0010 | MIPI1 | 256 BYTE | 0x0200 ~ 0x02ff |
| 4'b0011 | MIPI2 | 256 BYTE | 0x0300 ~ 0x03ff |
| 4'b0100 | MIPI3 | 256 BYTE | 0x0400 ~ 0x04ff |
| 4'b0101 | MIPI4 | 256 BYTE | 0x0500 ~ 0x05ff |
| 4'b0110 | MIPI5 | 256 BYTE | 0x0600 ~ 0x06ff |
| 4'b0111 | Scale/TOISP | 256 BYTE | 0x0700 ~ 0x07ff |
| 4'b1000 | MMU0 | 256 BYTE | 0x0800 ~ 0x08ff |
| 4'b1001 | MMU1 | 256 BYTE | 0x0900 ~ 0x09ff |

## 37.4.2 Registers Summary

| Name | Offset | Size | Reset Value | Description |
|---|---|---|---|---|
| VICAP_GLB_CTRL | 0x0000 | W | 0x00010001 | VICAP global control |
| VICAP_GLB_INTEN | 0x0004 | W | 0x00000000 | VICAP global interrupt enable. |
| VICAP_GLB_INTST | 0x0008 | W | 0x00000000 | VICAP global interrupt status. |
| VICAP_DVP_CTRL | 0x0010 | W | 0x00000000 | DVP path control |
| VICAP_DVP_INTEN | 0x0014 | W | 0x00000000 | DVP path interrupt status |
| VICAP_DVP_INTSTAT | 0x0018 | W | 0x00000000 | DVP path interrupt status |
| VICAP_DVP_FORMAT | 0x001C | W | 0x00000000 | DVP path format |
| VICAP_DVP_MULTI_ID | 0x0020 | W | 0x00000000 | Channel ID for multi-ID mode |
| VICAP_DVP_SAV_EAV | 0x0024 | W | 0xFEDCBA98 | SAV/EAV for ACT/BLK |
| VICAP_DVP_CROP_SIZE | 0x0028 | W | 0x01E002D0 | The expected width and height of received image |
| VICAP_DVP_CROP_START | 0x002C | W | 0x00000000 | The start point of DVP path cropping |
| VICAP_DVP_FRM0_ADDR_Y_ID0 | 0x0030 | W | 0x00000000 | DVP path frame0 y address |
| VICAP_DVP_FRM0_ADDR_UV_ID0 | 0x0034 | W | 0x00000000 | DVP path frame0 uv address |
| VICAP_DVP_FRM1_ADDR_Y_ID0 | 0x0038 | W | 0x00000000 | DVP path frame1 y address |
| VICAP_DVP_FRM1_ADDR_UV_ID0 | 0x003C | W | 0x00000000 | DVP path frame1 uv address |
| VICAP_DVP_FRM0_ADDR_Y_ID1 | 0x0040 | W | 0x00000000 | DVP path frame0 y address for ID1 |

*Notes: I=input, O=output, I/O=input/output, bidirectional*

Furthermore, different IOs are selected and connected to different flash interface, which is shown as follows.

# 37.6 Application Notes

## 37.6.1 DVP Interface

- The MSB 4 bits of SAV/EAV of BT.656/BT.1120 are configurable, and the default values of SAV/EAV abide by the agreement.
- The sw_only_sav_mode for BT.656/BT.1120 is more robust for the case that the EAV is wrong.
- User can read the register of ro_sync_header_0~ro_sync_header_7 to obtain the recent 8 SAV/EAV.
- In the multi-ID mode the LSB 4 bits of SAV/EAV are used to distinguish ID. In most cases the LSB 2 bits of SAV/EAV are ID number, in these cases the register sw_chid_bit_en should be configured as 4'h3.
- The register sw_yuyv_in_order should be configured correctly. In the BT.1120 case 2'h0/2'h2 are the same for UV sequence and 2'h1/2'h3 are the same for VU sequence.
- In the dual-edge sampling case, the SYS_GRF_SOC_CON2[5] must be set to 1, and the register sw_dualedge_en must be set to 1. The clock phase could be adjusted by setting the SYS_GRF_SOC_CON3[7:0].

## 37.6.2 MIPI Interface

- The register sw_crop_en is suggested to be set to 1. The register sw_width/sw_start_x should be aligned to 4.
- In the sony identification code hdr mode, the register sw_sony_effect_code0/1 should be configured correctly according to the camera manual.
- In the line counter hdr mode, the register sw_on_pad_value should be configured correctly according to the camera manual.
- In the VC hdr mode, the register sw_vc_hdr_protect is suggested to be set to 1, and the register sw_vc_hdr_id_main should be configured as the first coming id that is the long exposure frame id.
- The register sw_cap_en_idx is recommended for static configuration, and the register sw_cap_en is recommended for dynamic configuration.

## 37.6.3 Scale down

- The register sw_scl_chx_black_00/01/10/11 is the black level value for bayer pattern 00/01/10/11 position.
- The bit width of scale down output data is 16. When the max bit width of the scale down output data exceed 16, output data will be clipped. For example, 8 times scale down for RAW12, the bit width is 18, then the result will be clipped to 16 bits.
- When the width is not a multiple of double scale down times,then the result will be rounded up to an integer. For example, the image width is 4656 and 32 times scaling down is performed, the result width equals to (ceil(4656/64)*64)/32.
- When the height is not a multiple of double scale down times, then the result will be rounded down to an integer. For example, the image height is 1080 and 8 times scaling down is performed, the result height equals to (floor(1080/16)*16)/8.

## 37.6.4 TOISP

- The register sw_width/sw_start_x should be aligned to 4.
- Although there are three channels to ISP, user just need enable channel 0 and select the short exposure frame id.

Copyright 2022 © Rockchip Electronics Co., Ltd. 

### 37.6.5 DMA

- The start address/virtual stride should be aligned to 8 at least. And being aligned to 64 is good for DDR.
- User could shut down DMA transferring by setting the register sw_dma_en to 0.
- User could set sw_hurry_en/sw_press_en to 1 for dynamic adjusting the priority of VICAP. And the register sw_water_line is the triggering condition of pulling up hurry/press signal.
- For DVP path the register sw_yuyv_out_order is effective when the register sw_wrddr_type is NV16/NV12/YUYV. And in the NV16/NV12 case, 2'h0/2'h2 are the same for UV sequence and 2'h1/2'h3 are the same for VU sequence.
- For MIPI path the register sw_yuyv_out_order is effective when the register sw_wrddr_type is YUYV. And in the NV16/NV12 case, sw_yuyv_out_order need to be configured as the same as sw_yuyv_in_order.
- There are two modes for line counter interrupt.In one-time mode, if line_int_num =100, the line_intst will be 1 when receive 100th line. In circular mode, if line_int_num =100, the line_intst will be 1 when receive 100th line200th line300th line.....
- There are two AXI masters and two MMUs in VICAP. The AXI_0/MMU_0 are used for MIPI_0/MIPI_2/MIPI_5/SCALE, and the AXI_1/MMU_1 are used for MIPI_1/MIPI_3/MIPI_4/DVP.

### 37.6.6 Reset

- DMA will be auto-reset when DMA goes wrong, for example fifo overflow. And DMA will transfer data from the next frame.
- DMA also could be soft-reset by the register sw_dma_rst.
- User could reset the entire data path (interface/dma) by setting the register sw_soft_rst to 1. And the scale/toisp module will be reset if the sw_scl_mux/sw_toisp_mux is setted to choose the path.

# Chapter 38 FishEye Correction(FEC)

## 38.1 Overview

FEC supports the following features:

- Input mode and data format
  - Support RASTER: YUV422SP, YUV422I, YUV420SP
- Output mode and data format
  - RASTER: YUV422SP, YUV422I, YUV420SP
  - FBCE: YUV422SP, YUV420SP
- Support 16x8, 32x16 two density
- Support up to 4 times reduction factor
  The basic unit of the destination end is 16x16 and 32x32. For the larger distortion uses 16x16, and the smaller distortion uses 32x32. When the corresponding source exceeds 64x64, then directly fills Y=0, U=128, V=128
- Support level interrupt
- Support 32bit AHB
- Support 128bit AXI
- Support 128bit MMU, MMU affect FEC performance, it is recommended to close MMU
- Input resolution 128x128~8188x8188
- Output resolution 128x128~4096x4096
- Source width and height must be x4
- Destination width and height must be x4
- Y Interpolation: Bicubic; C Interpolation: Biliner

## 38.2 Block Diagram

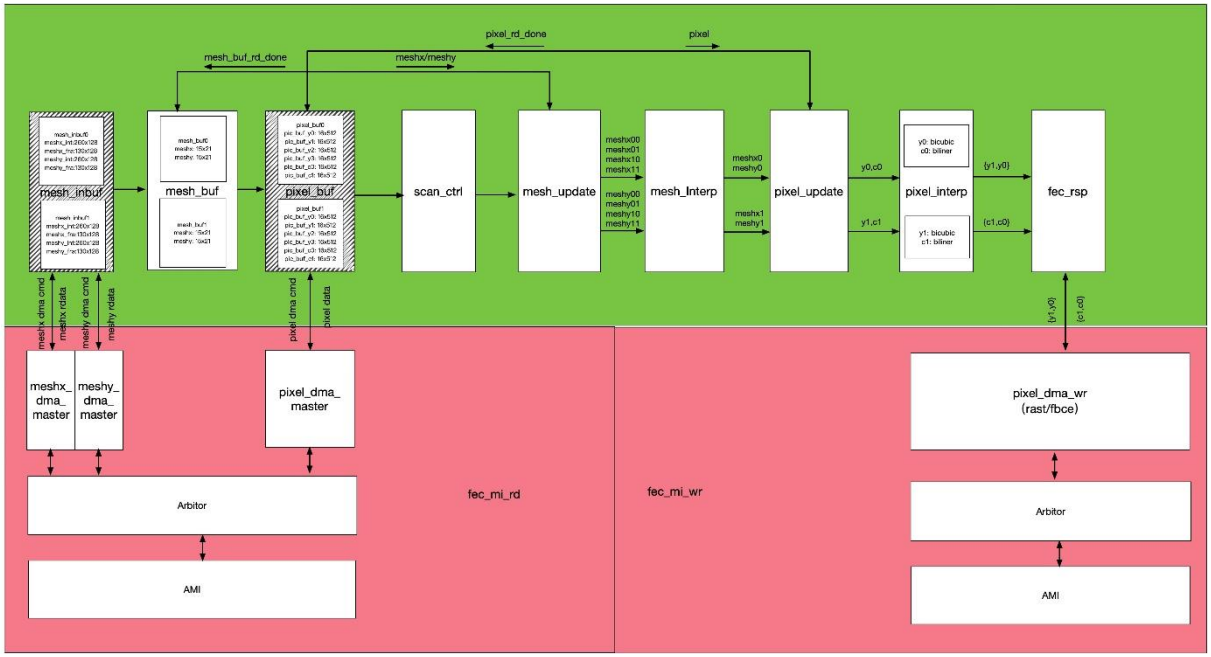

Fig. 38-1 FEC Block Diagram

## 38.3 Function Description

The principle of FEC is to obtain the corresponding source data according to the meshgrid requirements, and then perform interpolation according to the corresponding coefficients, as shown in the following figure:

Copyright 2022 © Rockchip Electronics Co., Ltd. 

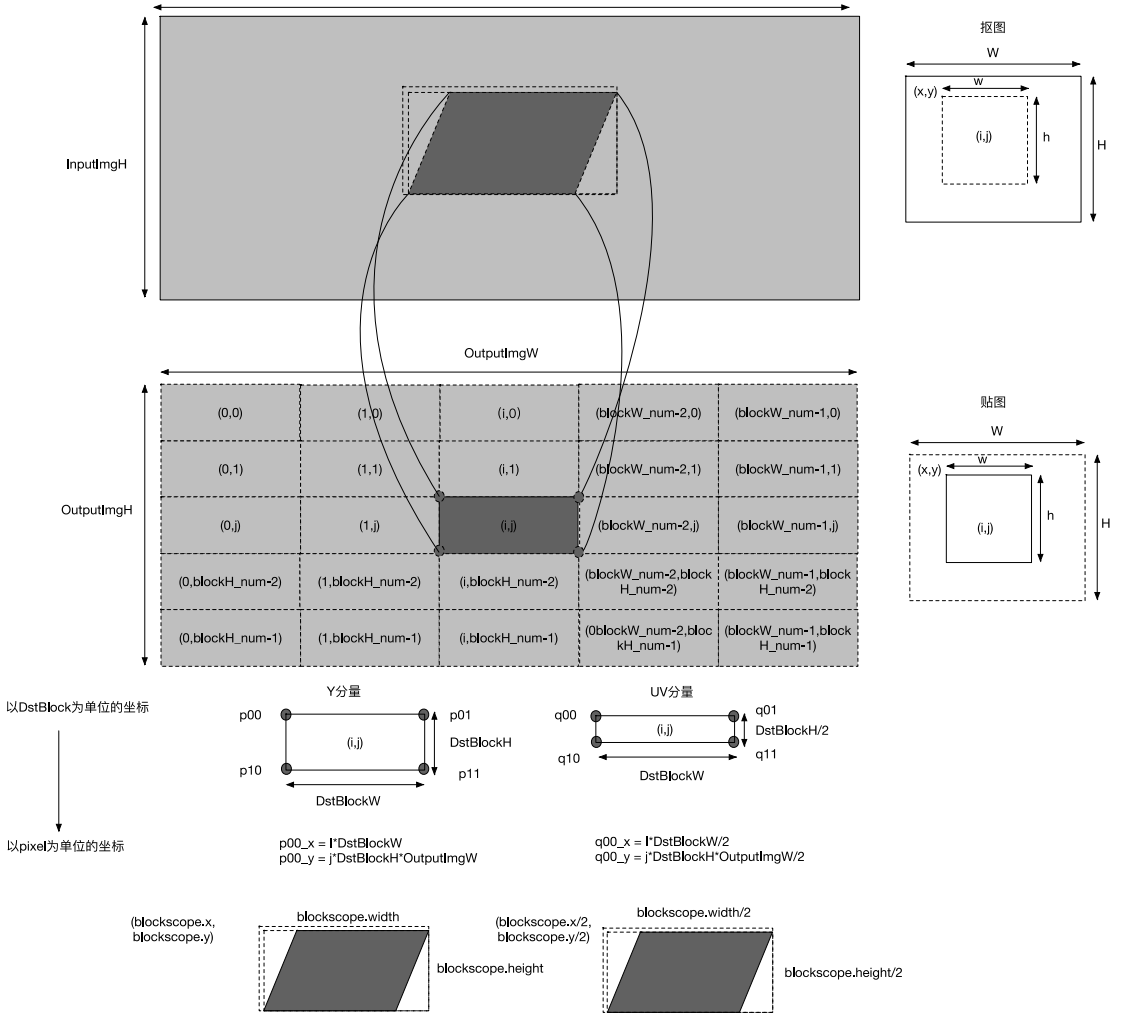

Fig. 38-2 FEC function description

1、 You need to align the resolution to 32x32 firstly, and then down-sample according to the meshgrid density of 16x8 or 32x16

2、 Decimals meshgrid and integer meshgrid are stored separately, and the address must aligned to 16B

3、 And due to the pixel scan, in order to achieve the maximum efficiency of using the grid, the meshgrid timing needs to be overlapped, according to the 32x128 block, as shown in the following figure:

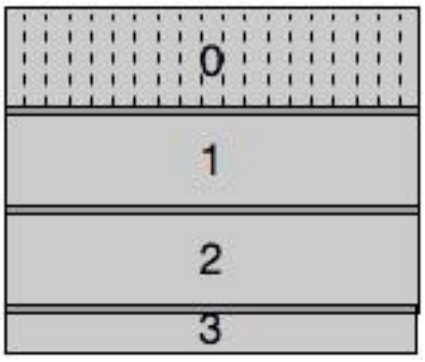

Fig. 38-3 FEC meshgrid overlap

4、Consistent with the pixel scanning, the meshgrid can be used with maximum efficiency

## 38.4.2 Detail Register Description

### FEC_ISPP_START

Address: Operational Base + offset (0x0000)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:3 | RO | 0x00000000 | reserved |
| 2 | W1C | 0x0 | sw_fec_st<br>ISPP command start |
| 1:0 | RO | 0x0 | reserved |

### FEC_ISPP_UPDATE

Address: Operational Base + offset (0x0004)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:3 | RO | 0x00000000 | reserved |
| 2 | W1C | 0x1 | sw_cfg_force_upd<br>ISPP register force update for FEC |
| 1:0 | RO | 0x0 | reserved |

### FEC_ISPP_RESET

Address: Operational Base + offset (0x000C)

| Bit | Attr | Reset Value | Description |
|---|---|---|---|
| 31:22 | RO | 0x000 | reserved |
| 21:16 | RW | 0x00 | sw_glb_init_dis<br>Hardware will reset automatically at frame start if the module Corresponding bit set to 0 |
| 15:12 | RO | 0x0 | reserved |
| 11:8 | RW | 0x0 | sys_reg_msoft_rst<br>Scale hardware will reset automatically at frame start if the module Corresponding bit set to 0 |
| 7:2 | RO | 0x00 | reserved |
| 1 | RW | 0x0 | sw_rst_protect_dis<br>Safety reset select<br>1'b0: Protect reset<br>1'b1: Direct reset |
| 0 | W1C | 0x0 | sw_glb_soft_rst_all<br>FEC soft reset with self-clear |

# 38.5 Application Notes

## 38.5.1 Setup Flow

- setting meshgrid information
  - sw_mesh_xint_base, aligned to 16B
  - sw_mesh_xfra_base, aligned to 16B
  - sw_mesh_yint_base, aligned to 16B
  - sw_mesh_yfra_base, aligned to 16B
- setting source information
  - setting sw_pic_y_base/sw_pic_c_base, aligned to 16B
  - setting source format YUV420/YUV422/YUV422I
  - setting sw_fec_src_width, sw_fec_src_height
  - setting sw_rd_vir_stride, word unit, aligned to 16B
- setting destination information
  - setting sw_wr_y_base/sw_wr_uv_base, aligned to 16B
  - setting destination YUV420/YUV422/YUV422I
  - setting sw_fec_act_width, sw_fec_act_height
  - setting sw_wr_vir_stride, word unit, aligned to 16B
- set sw_cfg_force_upd for FEC
- set sw_fec_st

## 38.5.2 Note

- It is recommended malloc one line more than original source buffer in DDR. For example, 1920x1080 source recommended 1920x1081 in DDR. When the boundary is accessed, since the internal DMA accesses at least 16 pixels, it may access the data of the next line.
- It is recommended that MMU is turned off to improve performance.
- Max mesh value must <= 8189

# Chapter 39 Pulse Density Modulation Interface Controller

## 39.1 Overview

The PDM interface controller and decoder support mono PDM format. It integrates a clock generator driving the PDM microphone and embeds filters which decimate the incoming bit stream to obtain most common audio rates.
There are two PDM controllers in the SOC. PDM0/PDM1 both support the following features:

- Support one internal 32-bit wide and 128-location deep FIFOs for receiving audio data
- Support receive FIFO full, overflow interrupt and all interrupts can be masked
- Support configurable water level of receive FIFO full interrupt
- Support combined interrupt output
- Support AHB bus slave interface
- Support DMA handshaking interface and configurable DMA water level
- Support PDM master receive mode
- Support 4 paths. Each path is composed of two digital microphone channels. It can be used with four stereo or eight mono microphones. Each path is enabled or disabled independently
- Support 16~24-bit sample resolution
- Support sample rate: 8kHz,16kHz,32kHz,64kHz,128kHz,11.025kHz,22.05kHz,44.1kHz,88.2kHz,176.4kHz,12kHz,24kHz,48kHz,96kHz,192kHz
- Support two 16-bit audio data store together in one 32-bit wide location
- Support 16 to 31-bit audio data left or right justified in 32-bit wide FIFO
- Support programmable left and right channel exchange

## 39.2 Block Diagram

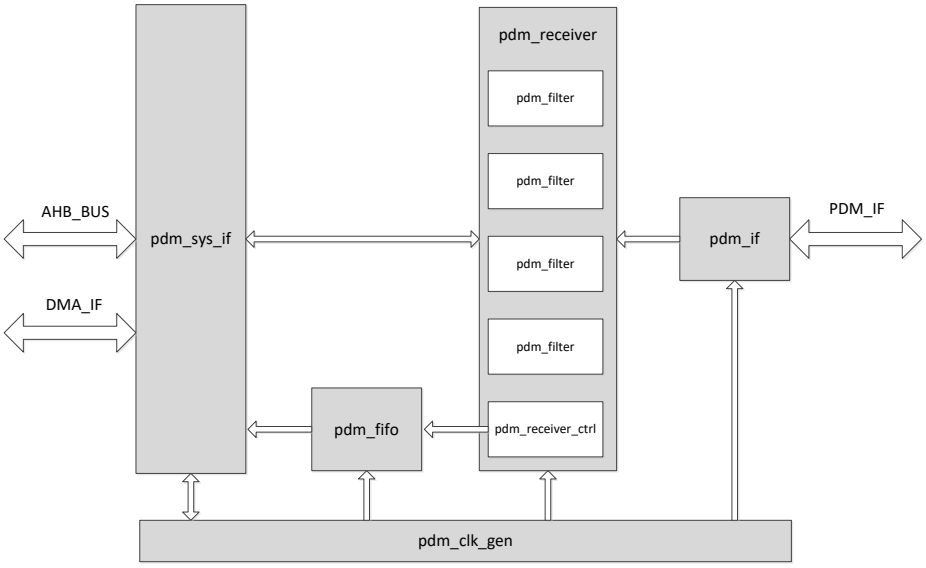

Fig. 39-1 PDM Block Diagram

**System Interface**
The system interface implements the APB slave operation. It contains not only control registers of receiver inside but also interrupt and DMA handshaking interface.
**Clock Generator**
The Clock Generator implements clock generation function. The input source clock to the module is MCLK, and by the divider of the module, the clock generator generates CLK_PDM to receiver.
**Receiver**
The receiver can act as a decimation filter of PDM. And export PCM format data.
**Receive FIFO**
The Receive FIFO is the buffer to store received audio data. The size of the FIFO is 32bits x 128.

# 39.3 Function Description

## 39.3.1 AHB Interface

There is an AHB slave interface in PDM. It is responsible for accessing registers.

## 39.3.2 PDM Interface

The PDM interface is a 5-wire interface. The PDM module can support up to four external stereo and eight digital microphones.

Following shows two cases of usage of the PDM, but all configurations are possible with stereo and mono digital microphones.

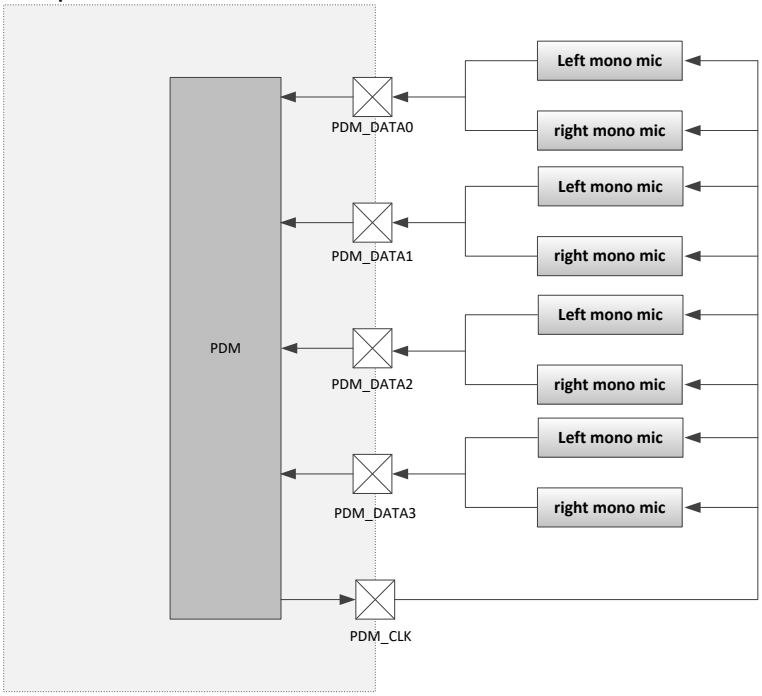

Fig. 39-2 PDM with Eight Mono MIC

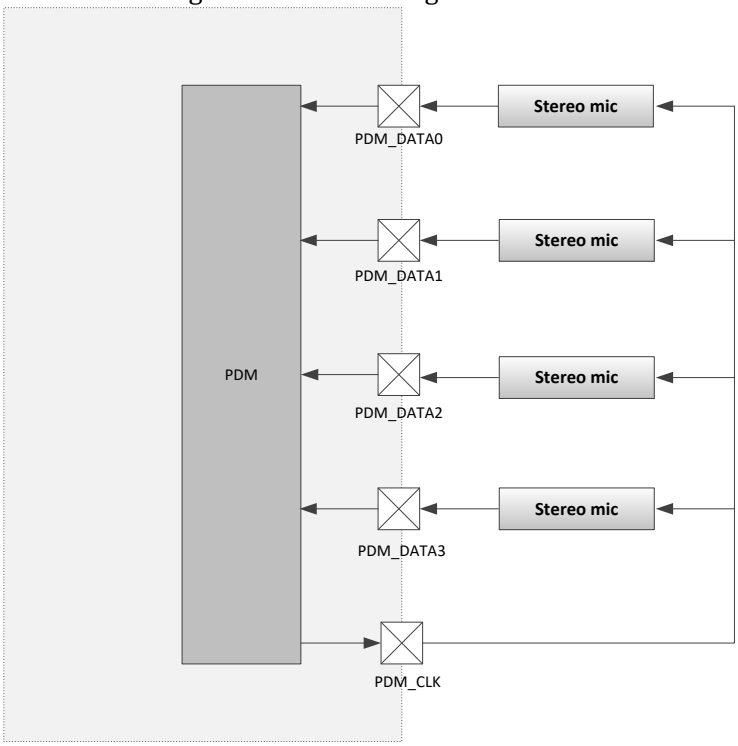

Fig. 39-3 PDM with Four Stereo MIC

The PDM interface consists of a serial-data shift clock output (PDM_CLK) and a serial data input (PDM_DATA). The clock is fanned out to both digital MICs, and both digital MICs' data

Copyright 2022 © Rockchip Electronics Co., Ltd. 

(left channel and right channel) outputs share a single signal line. To share a single line, the digital MICs tri-state their output during one phase of the clock (high or low part of cycle, depending on how they are configured via their L/R input).

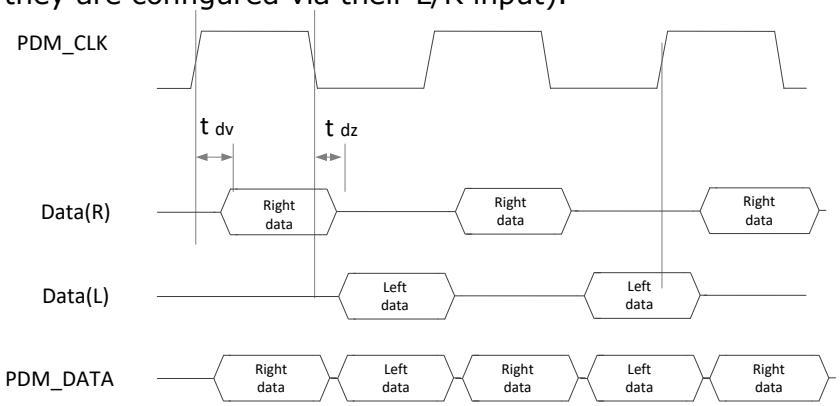

Fig. 39-4 PDM interface diagram with external MIC

### 39.3.3 Digital Filter

The external PDM MIC generates a PDM stream of bits and transfers it in one period or one half-period of the clock provided by the PDM. The aim of the PDM is to process data from the PDM interface, decimate and filter the data, and store the processed data in the FIFO.

The four paths are identical. Each path is composed of a left and a right channel. The PDM interface delivers eight parallel data of 1bit. Each bit goes to a filter. The aim of the filter is to limit the noise and export PCM format audio data.

### 39.3.4 Frequency Configuration

MCLK is the source clock signal. PDM_CLK is the output clocks generated in the PDM and is fed to the external microphones. They are also the internal clock of the external microphones. User must take care about the frequency of PDM_CLK when selecting the source clock (MCLK).

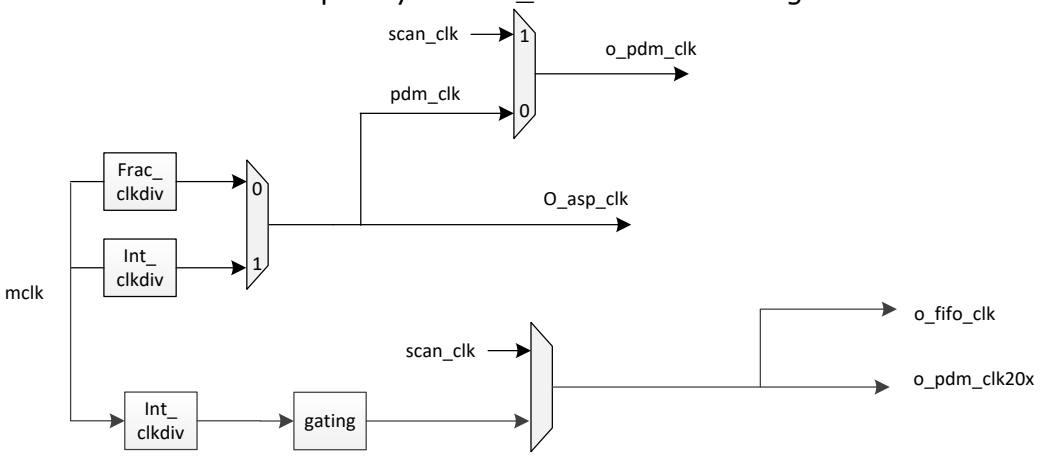

Fig. 39-5 PDM Clock Structure

Table 39-1 Relation between PDM_CLK and Sample Rate

| PDM_CLK | Sample Rate |
|---|---|
| 3.072MHz | 12kHz,24kHz,48kHz,96kHz,192kHz |
| 2.8224MHz | 11.025kHz,22.05kHz,44.1kHz,88.2kHz,176.4kHz |
| 2.048MHz | 8kHz,16kHz,32kHz,64kHz,128kHz |

## 39.4 Register Description

### 39.4.1 Internal Address Mapping

Slave address can be divided into different length for different usage, which is shown as follows.
